Finally, I add this all up to get received power (Pr);

Pr = EIRP - Lp + Ga - Lf where Ga is antenna gain (in dBi) and Lf is feed line loss (in dB).

Pr = 82.14 - 112.876 + 10 - 4 = -24.736bBm, or about 3 microwatts.

Assuming the voltages are all referenced to a 75 ohm load, 3 microwatts = 15 millivolts, or -18dBmV. A long way from 33dBmV.

Based on Ian's and Georges reply, I think I need a better understanding of how the basic receiver characteristic, NF (noise figure), relates to received signal strength.

You can always put a mobile antenna on your car and then run coax from the shack to the car. I know a few people who have done that at various times and it worked well. At least it gets you outside. Also, once outside, you might find a place to set up a small vertical (quarter wave) of fine wire -- it would only be 11 ft high for 15m or 8 ft high for 10m. On those bands, the car mobile antenna would probably work just as well.

Let me ask this, what's wrong with running the ladder line right to the tuners balanced output? Is the coax used only to keep the ladder line outside so it won't have to come through a window? How far from the edge of the window does the ladder line have to be to be considered safe and have no interaction? (talking a 100 watt station and alum frame windows). Getting ready to put up (weather permitting) phased dipoles for 20 today.

And can someone tell me if a Kenwood AT-250 has balanced output for ladder line? A friend is thinking of buying a TS-440 with a AT-250.

Kevin

Here is my 2 cents worth . I have run similar setups in my 4x4 / truck . I use an 8 GA wire (2 conductor) right from the battery to power the rig .

On antenna`s . For under $ 20.00 , use a Francis 108" whip and add a little length to it .
For under $ 60.00 , buy a Wilson 1000 and get a
longer whip for it , this is what I have used and it works great ! Bandwidth is really good as well .

Glad to see someone else likes the simplicity of the 10 meter rigs for communication on the road , not all
of us Amatuers can WASTE 1000`s of dollars on our mobiles.

What specific claim made by Kraus are you claiming to be incorrect? I've
been over the entire chapter on loop antennas in both Kraus and Balanis,
who both make essentially the same observations. While not completely
general (especially Kraus), the derivations appear ironclad (to me
anyway), given the constraints on current distribution discussed in the
text.

> Mr.
> Best has discovered for himself that the SLA will not only predict the rad

Are you referring to the small loop approximation in Kraus? As far as
radiation resistance is concerned, I don't see that it applies to the
various antenna's you or Steve have been discussing in the context of
the 'challenge'. Kraus makes it clear from the text and illustrations
that his small loop approximation for radiation resistance applies only
to the case of uniform loop current.

The current is not uniform in either your M12, or Steve's arbitrary
arrangements. Therefore, Kraus's derivation of the radiation resistance
for a small loop simply does not apply.

Kraus also makes the more general statement that the radiation from any
small loop of arbitrary geometry (and current distribution) is
proportional to the magnetic moment developed by the current. This
relationship follows directly from the classical formulation of the far
field vector magnetic potential. The only approximation is that the
physical extent of the antenna must be small enough so that the
variation in phase retardation across the antenna is negligable.

I just picked up an older rig and need to get a frequency counter for it .
Any suggestions as to whats good for NEW ones or what are the older
favorites or reliable ones ? I am looking at a older Heathkit IM-2410 ,
whats it worth or should I just buy new ? I dont want to spend tons of money
on it either. Anyone have a good one forsale ? Thanks a bunch

> 20log(191.1815) = 112.876dB

You are using the formula for free space path loss where the received signal power decreases by 20 dB per decade in distance. The formula does not take into account the destructive interference from the component of the received wave which is reflected off the nearby ground and will usually overestimate the received signal strength. In the realistic case where the ground reflection is unattenuated, the received signal strength falls off at a rate of 40 dB per decade in distance and increases 20 dB per decade of antenna height.

Real world path losses are usually somewhere in between the two cases.

Agreed. The point is this does not apply to all small loops and characterizing the rad resistance by area is inaccurate.

>> Mr.
>> Best has discovered for himself that the SLA will not only predict the rad
>> resistance incorrectly, but similar values of rad resistance are obtained
>with

>various antenna's you or Steve have been discussing in the context of
>the 'challenge'.

It most certainly does not apply because it is an incorrect generalization for small loops. THAT is the point.

Note that on the other extreme, Kraus also talks about the rad resistance of large loops, again taking a 'uniform current' appropximation, which in most cases is surely not viable. Yet the values obtain are reasonable approximations. They are not reasonable approximations for small loops--characterized by area.

< Kraus makes it clear from the text and illustrations
>that his small loop approximation for radiation resistance applies only
>to the case of uniform loop current.
>

No; he also discusses multi turn loops, for example, which are by no means
uniform.

>The current is not uniform in either your M12, or Steve's arbitrary

Absolutely!

<Therefore, Kraus's derivation of the radiation resistance
>for a small loop simply does not apply.
>

EXACTLY!

>Kraus also makes the more general statement that the radiation from any

>

That comment does not help vis a vis understanding a small loop. The point is
that a multi current max resonant loop which is electrically small is a
previously unknown--or at least little studied --beast. Perhaps you can help us
with a ref Bart? Could be much obliged.

I am a little confused on why you are lengthening the antennas. It is
my experience that 10 meteres is a shorter wavelength than 11 and
requires a shorter whip.

The answer is YES. During WW2 yours truly was called upon to repair a 19
set installation in a tank... it would receive but not send. It had been
assumed that it wasn't sending because nobody could receive it. My
examination showed "no fault found". The tank was under a tree and
camouflaged. Moving it a few feet away from the tree resolved the peoblem.

Jeff,
Why is it a waste even if you didn't spend 1000's as you put it. You get what
you pay for as far as a dedicated mobile rig. I run an FT 100 Base/Mobile and
don't think it was a waste, AND I run 10/2 meters only mobile.

Kevin,
The Wilson line of antennas are very good for what you want. In fact even the LIL Will is a pretty good 10 meter antenna. The Wilson 1000 Has about a 3 meg band width with < 2:1 SWR. I use one Mag mount with an FT 100 and It does a very good job.
73 and I'll be happy to help in any way I can.

I am in the Kettering,Ohio area and I would like to use my television on channel 59 or I have a converter to pick up ametuer television.I was wondering if someone would have some ideas on what type of antenna to use to pick this up?Thank`s for any info,Rob.

I agree with Bill. I had a 11/10 meter antenna on my suburban... you've seen them, they have the big open coils that look really cool and don't work worth a hoot. I went to the ham fest and bought myself ham sticks for 10, 20, and 40 meters. The glorified CB antenna had an SWR of 2.5-1 tops and I worked several contacts (spent a lot of time listening to get used to the difference between HF and 2 meters).

When I hooked the ham stick up I didn't even need to have the preamp on in my IC706. I could not believe the difference. I worked France the other day and now I can hear both sides of the conversation most of the time... probably why I didn't talk much because I could never hear the other side of the QSO so I didn't know when to call the station I could hear. They make a great mount for pickups advertised in ARRL magazine. I use quick disconnects (push, twist& lock) incase I need to get into parking garages or don't want the antenna out there when parked in the city, etc... you get the picture.

My advise, buy a hamstick or something made for ham radio. You don't have to spend a fortune to have a good time. I'm sure I could do better with more elaborate antennas, but I've seen a lot of HF antennas on vehicles and don't want all of that hanging on my suburban which I use in my business.... nothing wrong with that... just a matter of preference.

Good luck, if you need the names of the quick disconnects or the pickup bed mount (goes in the rack channels of your bed) let me know. Ham sticks are around 20 bucks, low profile and cheap enough to determine if you want to spend more later to get real serious.

The rim would still act as a shorted secondary.

Should work ok if the rim were cut in one place and a bit of insulation
inserted, as is customary with shielded loops with the turns inside some
sort of metal tubing.

I'd like to talk about the manual with you. Apparently some portions are misleading, and I'd like to correct them. If you'd email me, mentioning which sections led you to these conclusions, I'd be very appreciative.

> Here is my thinking.
>
> 1. The EZNEC program splits the antenna up into stright line "segments" and
> in the professional and registered versions this can be done automagically.

The user makes the antenna from straight wires, and the length, position, and orientation are completely up to the user. The user then tells the program how many "segments" to divide these shorter wires into. Both the standard and professional versions allow the number of segments to be determined automatically, but I recommend using this feature with care. A number of factors is involved in determining the best number of segments, which the simple-minded automatic segmentation system doesn't take into account.

> 2. You do not get to see the segments it chooses.

This is not correct. The number of segments appears in the Wires Window. There, you can choose, and see, how many segments each wire is divided into. In the View Antenna display, the segment junctions are shown as dots of a color of your choice.

> 3. Antenna wires in the model can only be straight lines.

This is correct.

> 4. A fractal to me is a shape of the same form within a shape (often

> straight bits (i.e. "steps") making up the arc.

> 7. These steps are in fact smaller versions of the larger shape, and inside
> that shape - thus fullfilling my criteria for a simple fractal design.

It sounds like you have the impression that EZNEC (or ELNEC, which is
now obsolete) models some other shape than the one you've entered, and
substitutes straight wires or other wires from the ones you've
specified. It does not. It analyzes the shape you entered and no
other(*). You have full control over both the antenna shape and the
segmentation. The segments are not independent of the wires, but are
subdivisions of the wires which you specify.

> You may of course want to dissagree with this.
>
> 8. With a more complex "arbitary" shape where there is lots of wire in a
> small space in arbitary form this effect is magnified (rather than reduced)
> because ELNEC / you will chose straight lines it can handle.

Again, you choose the wires. The program doesn't.
>
> This is why I suggest to be careful.

One should always be careful when modeling, but I think your objections
are based mostly on misconceptions about how EZNEC works. Thanks very
much for taking the time to elaborate, so I could understand your
concerns.

I highly recommend that you, or anyone who has questions about how EZNEC
works, download the free demo and actually use it. And I'm always glad
to answer questions, with the only request being that you first make an
honest effort to find the answer in the manual.

Roy Lewallen, W7EL

(*) EZNEC will in some special cases analyze wires of different length
and diameter than the ones you've entered. NEC-2, which EZNEC uses for
calculations, is known to produce a small error when analyzing connected
wires of different diameter. This isn't large enough to be a problem in
most cases, but it is if the wires are part of a parasitic element, such
as in a Yagi element made from telescoping tubing. In special cases
where the element is straight, symmetrical, and close to half wave
resonance (or quarter wave resonance for a grounded element), EZNEC will
substitute an element of constant diameter and equivalent length which
will perform the same and be capable of accurate analysis. I call this
"stepped diameter correction". This process can be disabled if desired.
When it's active, the calculation window will show that the process is
being used, and you can see in the Wires Window exactly what
substitutions were made. Results from this substitution (using the
method developed by Dave Leeson, W6QHS in his book _Physical Design of
Yagi Antennas_) are very close to results using NEC-4 without the
substitution. NEC-4 is relatively free from the error.

Jeff:

If the "older rig" is running AM, then almost any freq counter will work...just hook the counter into one of the low level driver stages with a small coupling capacitor. Of course, use caution around high voltages.

If the "older rig" is an SSB transceiver, you should be aware than an ordinary freq counter will only display the frequency of the stage it is coupled to, which will not be the actual frequency of operation. To display the actual operating freq, you need a counter with the ability to add or subtract the IF freq. Such counters exist, but they are specially designed to do this job.

One such counter can be obtained from: http://www.aade.com/

Actually, just about everyone has to meet the RF exposure requirements, your commercial radio provider, as well. However, mobile, "push-to-talk" installations are exempted from filing a survey because they're not on the air long enough, in one place, to likely exceed the SAR for public exposure. This includes your mobile 6 meter rig.

Looks like the neo-Luddites won this round. It doesn't come out of a
box ready to run, so kill it. So much for experimentation.

I subscribed to this NG in hopes of seeing information on advances
in antennas, because Hams are historically famous for thinking outside
the box.

Instead I find a bunch of people who give rednecks a bad name.

Bye.

Arron Hanson wrote:
"I am considering purchasing an antenna for the specific purpose of TV reception of CBUT (Vancouver Canada Channel 2) from Seattle."

Can you use the Space Needle to mount your antenna?

There is slim to no chance of a 140-mile terrestrial line of sight path. You would need 2450 feet of antenna height on each end of a smooth earth path with zero Fresnel zone clearance and no allowance for abnormally poor atmospherics.

Your best hope is atmospheric refraction and forward scatter. It happens, but you need the best antenna you can get to make it happen regularly.

The path loss over a 140-mile Channel 2 line of sight path is tolerable. You lose 22 db in the first wavelength (about 18 feet), then you lose an additional 6 db every time the distance doubles after that. The total for 140 miles is about 118 db of loss.

If the transmitter ERP were 100KW in your direction, that would be plus 80 dbm.

The absolute difference between path loss and transmitter output is a small 38 db. With no reeiving antenna system gains or losses, that -38dbm is the receiver sensitivity required, because if the path were clear that would be the received carrier power. Any TV receiver should be much better than that.

The problem is that the propagation tends to be line of sight.

Best regards, Richard Harrison, KB5WZI

Hello again, and thanks for the advice so far. I wanted to make a few clarifications about my setup though. I intend to use my G5RV on ALL HF bands (10-80, including WARC). The antenna has 102' of "flat-top" to it, and about 30 feet or so of 400 ohm laddeline which is connected to a balun, after which there is about 70 feet or so of rg-8x. If precise measurements are needed, I can provide some. I am aware that certain lengths of coax can increase the SWR, but if memory serves, the length I have is one shown to be within an acceptable SWR range (although the SWR is still really high in spots).

My main concern was that my new rig's autotuner would fail if too great of an SWR is shown to it.

Thanks for your patience on this matter...I am slowly but surely learning the "HF ropes", as I am more experianced with VHF antenna systems.

Adam

Just one rule-of-thumb hint. At the receive end, a halfwave dipole for
appx 50 MHz (is it more like 47?) in a fieldstrength of 1V/m gives you
1V (60dBmV) into 75 ohms (ie the centre of the antenna when terminated
in 75 ohms). At appx 100MHz, for a halfwave dipole, you get half as
much, etc, etc...

Ian.

John S. McKay wrote:
"Moving it away from the tree resolved the problem."

The Type 19 tank set was a combo of two radios, one 2 to 8 MHz, or thereabouts depending on late or early production, and another, a UHF radio, operating 230 to 255 MHz.

Vertical trees next to vertical whips wouldn`t work well for either component radio set.

Best regards, Richard Harrison, KB5WZI

1392. 160M dipole feedline question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-29 22:51:17 UTC

Greetings,

Some of you have recently helped me by suggesting
a good compromise would be 264 ft. dipole feed by 450ohm
ladderline. Having trouble finding ladderline and no nearby
Hamfests upcoming until Jan./Feb. How would things change
if I used the Radio Shack 300ohm twin TV feedline? Believe
they advertise it as "low-loss, foam core". Thoughts? Don't
care about cost issues as I already have 100ft. of this stuff
laying around un-used. Also already have an un-used spool
of 14AWG insulated stranded and 6 egg-type insulators. Am
I about good to go ?

TIA,

Andrew

You should know, Richard, that Channel 2 transmits from more than 3,000
feet up on Mount Seymour, near Vancouver.

That makes some difference.

Bob.

Roland, I can quickly make a recommendation for the in-motion antenna
for 75 - 10:

DON'T !

I have been driving a large motorhome like yours for over ten years now,
and I strongly urge you to give up any thoughts of working HF mobile
while in motion. You need every ounce of your attention on driving.
Operating CB or 2-meters is one thing, where all you have to do is
concentrate on the PTT button on the mic, but HF has too many little
knobs and switches to distract you. Pleased reconsider any notions of
this operation. I think that any other motorhoming ham would give you
the same advice.

For parked operation I have mounted a standard Hustler mount on the rear
luggage rail. I shinny up the ladder and attach the Hustler mast with
antenna attached with a bayonet mount. Takes only about a minute once I
am parked.

I have worked the world with that arrangement. The large motorhome top
(mine is all metal) makes a great groundplane for the higher bands and
the large chassis gives lots of capacitance to ground for the lower
bands.

Let us know what you do.

: band width with < 2:1 SWR. I use one Mag mount with an FT 100 and It does a
: very good job.

Wouldn't that much bandwidth mean a low Q - which generally (for a mobile
antenna) translates to high ground losses (e.g. - poor radiation efficiency)?

WWVB is on 60kHz, I'm sure of it. It isn't WWV or WWVH, but rather a different
service with no voice broadcasting. If you go to the NBS site, you can
hopefully get a detailed description of the broadcast services offered.

Mark- your lack of analytical ability is remarkable- It is NOT
neo-Luddites that are against new antennas- it is rational humans who
are against a paranoid jerk.
You are also assuming it is some of the residents of this NG that caused
him grief- the real probability is that he did himself in, not any of
us. I have been surprised that Metro colloge kept him on this long.
HIs antennas may or may not be good- but we will never know from him,
because his main agenda is not technology, but Ego and the psychological
game called "uproar." If you look, you will find almost No technical
discourse from him- it is all blather. Almost all the technical content
of this NG is from others, not Cohen.
You should be more obsevant and look at the REAL reasons he is disliked,
and not attribute his position to rejection of new technology.

Go for it Andrew! I've used the "el cheapo" flat ribbon line for many years on 40 meters with excellant results. Assuming you have a good tuner, you have nothing else to buy. I now use the 450 ohm ladderline since a local electronics store carries it at reasonable price. Good luck.

So what you do about that is run PARALLEL dipoles, such that one of
them always presents a modest SWR on all bands of interest. 80,40, and
twenty meter dipoles paralleled on a single coax run do a quite good job
of covering the HF bands here.

Thanks Kirby, I have been thinking a bit about how I can hang a long wire up in the apt. I just thought that if the long wire streached and twisted around the apartment that would be bad in some way. I know enough not to double the thing back on itself but as far as right angles and all that, I haven't a clue. I did tie my electrical ground to the rig and little good that did. I also noticed that I coulda smoked my power supply had I hooked that up. Finnally got the grasp of electrical and rf grounds. (somewhat) I appreciate you help and I'll try experimenting with longwires and good rf ground for now!

Thanks!

You should read the other posts in this thread... or any other thread on the Fractenna topic for that matter and you'd probably get a different picture. I too thought he was getting a lot of grief when I came on this newsgroup, but by observation came to my own conclusion the NC really has some problems. Of course, everyone certainly has the right to draw their own conclusions.

Aaron,

Before you do anything, you will have to go to the library and get out some topographical maps. You MUST draw a line from your site to the transmitting site. What you will have to do is see how high your antenna will have to be to 'see' the transmitting antenna. From a later post, it looks like you are trying to receive a television signal from well over 100 miles away. In order to do this, the antennas must 'see' (or be very close to seeing) each other. You will have to draw that line and make sure that nothing in the intervening terraine obstructs that line. You will then have to do other calculations (involving Freznel zones) to arrive at your final path loss. I used to do this about 30 years ago and that is a long path - and is likely to be obstructed unless either you or the transmitter is VERY high or both you and the transmitter are quite high in the air. You will also have the curvature of the earth to consider. The problem, if you run into one, will not likely be the transmitter power, nor the receiver noise factor - it is likely to be obstruction of the path between your receiver and the transmitter. Best of luck.

73s,
Jim AA2QA

I used Radio Scrap twinlead. I bought the cheapest stuff they had because I just wanted to try feeding my dipole with "open wire" -- and it stayed up there for 13 years until I took it down. It was as good then as the day I put it up!

Ian Jackson, G3OHX wrote:
"At the receive end, a halfwave dipole for appx. 50 MHz (is it more like 47?) in a fieldstrength of 1 V/m gives you 1 V (60dBmV) into 75 ohms (i.e. the centre of the antenna when terminated in 75 ohms). At appx. 100 MHz, for a halfwave dipole, you get half as much, etc, etc..."

Good point. The power at a certain distance from the sender is in terms of physical area (per sq. mtr.) perpendicular to the direction of travel, not wavelength.

Also, the source of the power to the receiver has a resistance. It is the antenna`s radiation resistance. Maximum power transfer to the receiver requires a match between the receiver input resistance and the antenna`s radiation resistance. When there is a match, half the power is absorbed in the receiver`s input resistance, and half the power is re-radiated as the antenna`s radiation resistance. That`s the best it gets.

In Canada and the USA, TV Channel 2 occupies 54 to 60 MHz. Picture carrier is at 55.25 MHz. Sound carrier is at 59.75 MHz.

Best regards, Richard Harrison, KB5WZI

A trick from "the old days"

When using regular TV twinlead it will last longer (as if that is a problem in this case!) and be less resistant to rain detuning if you will coat the line with a good paste wax. We used to use Johnson's paste wax and really slather it on! <:}

For a better check, mount the antenna mast more or less horizontal with
the plane of the elements more or less vertical and the reflector next
to the ground. Just a few feet separation will be enough.

This will give you a better check of the tuning, SWR, etc.

Andrew,
You can use 300 ohm feed line with probably little
difference from the 450 ohm line. The maximum power
you can run with common TV twin-lead will probably be
less than with 450 ohm line.

But for crissake don't try to trim the individual flattops for low swr on their
own bands because they all interact and trimming one will make some other
dipole too long/short etc and you'll drive yourself nuts. BTW, don't try using
what cable companies and telcos use for 'lashing wire' to make antennas out of,
the manufacturers build a little resistance into the material in them and you
just cannot get the swr down. (drove myself nuts trying to once).

In most of the older tuners, the built-in balun is a 4:1 voltage balun designed to feed close to a 200 ohm load like a resonant loop or folded dipole. They are undersized for non-resonant dipole applications.

The standard G5RV does not work well on 30m, 17m, and 10m. However,
slight variations have a big effect on 10m. If you really want an
all HF band antenna, take a look at mine on my web page. Also follow
the G5RV web page selection to find out all about the G5RV.

Hi all,

Does anybody have (or know where I can get) plans for a dual band VHF/ UHF vertical antenna? Gain is not important, as there are a lot of local repeaters around that are easily accessible.

I would prefer not using an antenna switch as I already have beams for both bands and only one position left on the switch

Thanks in advance

Though the R.S. 300 ohm stuff will work fine, I perfer the 450 stuff mostly because of it's bigger stronger conductors.. here are a couple of web sights that have the 450 ladder line in stock.

During the Vietnam War Bell Laboratories ran some tests of a device which transformed trees into vertical antennas. The problem was that in the dense jungles of Vietnam the absorption was so great even at HF frequencies that small vertical whips were worse radiators than normal.

The Bell Labs engineer called his device a "HEMAC". That was an acronym for something but I can't remember what. The HEMAC was a loosly wound air-core toroid. The tree trunk went through the center of the doughnut formed by the torroid. The torroid coil was resonated with a variable tuning capacitor.

Comparative test results in a densely wooded area showed the HEMAC/tree had significant gain over an electrically short whip. I do not remember the numbers. A photo of this device being used on a tree on the Bell Labs campus appeared in a trade magazine but I never saw or heard of the device again. The accompanying short article said the same technique could be used to excite metal light poles. I would be interested in anything anyone in this group could add on this subject, especially references that might be accessible via the Internet. An Altavista search on HEMAC got 26 hits but none related to the device I remember seeing in that magazine.

The Heathkit balun coil shares a problem with a ferrite balun -
not enough inductance to handle all the impedances encountered
in a non-resonant, ladder-line fed doublet. I know of no multi-
band balun that will handle 2000+j2000 on 80m and 10m.

Someone here has missed the point completely. The problem with Chip et al is not that he has invented new technology which has been rejected by ANYONE on this NG, rather that he has consistantly and almost completely stonewalled against any and everyone here who has asked for real, hard information about his supposed invention. He repeatedly and very petulantly insists on directing all who ask to the most obscure of scientific writings which are mostly meaningless in deciphering any hard information on fractal shaped antennas as any improvement whatever over other shapes. He insists that the scientific literature supports his claims but so far has totally resisted any and all efforts to get him to tell us -right here- how and why.
It seems more than clear that when he can't or won't divulge, and almost all other respected and accepted antenna authorities fail to find any such attributes using the scientific references he quotes and their own scientific investigation, that his claims are vaporous at best, and a virtual scam attemp at worst.
If he was a serious scientist he would be more than pleased to make full disclosure, and we know that if his claims were valid it wouldn't be that hard to do.
Do I believe that fractal shaped antennas work? Of course- most any shape antenna will work.That's not the point of contention. Whether or not there is any advantage to those shapes-as is apparntly claimed by his writings and attempts to claim patents and copyrights- is the contentious area.

From here it looks like an attempt to force his claims onto the rest of the world, like it or not, by mostly bafflegab, bluster and threats of lawsuit.

Adam.
If you do end up using a G5RV, don't forget that Louis Varney designed it in the 40s for valve rigs (tune for max smoke etc). He updated the design several times, latterly using some co-ax as the original used only ladderline as feeder (and a special tuner). There are also several 'improved' versions with slightly different dimensions, redesigned using modelling programs. These allegedly work better and I think are ok on WARC bands. See various RSGB and ARRL antenna books. I am sure someone can confirm or deny the WARC bands bit.
Re possible damage to internal tuner. If a wire breaks and the swr departs skyward, my TS870 just shuts down and won't play.
Have fun

Because you just move the problem from the coax/ladderline transition point to the inside of the tuner, which in the case of every commercially built C-L-C tuner I've encountered, has a 4:1 toroid balun inside its cabinet, used to provide a balanced output. The problem of that balun seeing many impedances that it can't handle remains, and just moves inside the tuner cabinet.
No such problem will exist when using a coax/ladderline transition with a current (choke) balun. The only requisite is that the short section of coax and the tuner output variable capacitor must handle the high voltages present on frequencies where the antenna causes high reflected ratios.

I cut them for center band, separate them as much as possible,
avoiding close parallel installations and tune them with a tuner. It
has always worked for me.

That "carrier wire" is stainlss steel of high strength, and I never
pass an opportunity to grab it when available. I don't use it for
antennas but there are many other excellent uses for it.

IMO Nothing beats Copperweld for antennas. A few years ago I boubht a
spool of some new stuff called "Silky Smooth" or somethbing like that
from The Wireman. It was many small strands of plated steel and looked
like a good thing, and I repaced all my old copperweld with it. Turns
out it was NOT a good thing at all. I climbed the tower last week and in
looking things over and I see that ALL the entire length of each wire
element on all my antennas are now RUSTING! The plating is coming off
the small strands and over the entire length of every wire element small
points of rust are appearing. I'll have to replace every element on
every wire antenna, 160, 80, 40 and 30 meter dipoles. So much for
another "technological" advance! It's copperweld exclusively for me from
here on.

However, a "current (choke)" balun is just a marginally better solution,
not a perfect solution. No balun or choke that I know of will handle
2000+j2000 ohms on both 80m and 10m. One needs to know what impedances
the balun/choke is seeing. Link coupling in the antenna tuner is a much
better solution.

<A HREF="http://members.aol.com/_ht_a/Arrow146/inst/ijpole.html">J-Pole
Instructions</A>

Construction Plans for the Model J146/440 Dual Band Solid Aluminum J-Pole

Parts Needed:

Radio Shack # 21-961   3/8”-24/SO239 Mount (Mobile CB Antenna) Radio
Shack # 15-826   TV Mast U-Bolt Clamp Assembly
About 90 inches of 3/8” diameter Solid Aluminum Rod.
5 1/2 inch piece of strut angle Aluminum 1 1/2” X 1 1/2” X 3/16” Thick.
4 Stainless Jam Nuts 3/8-24 thread

Tools needed:

Drill Press with drill Bits up to 1/2”.
Tap & Die for 3/8-24 thread.
Sander or file to de-burr the cut edges.
2 9/16 wrenches & a 3/4 wrench. Vice-grips

Make sure the piece of angle Aluminum is exactly 5 1/2 inches long. Drill 2
1/4” holes on one side, centered to fit the U-Bolt for mounting. On the other
surface of the angle From the left side measure in 1/2” and drill a 1/4”
pilot hole. From the left side measure in 1 15/16” and drill a 1/4” pilot
hole. From the left side measure in 5” and drill a 1/4” pilot hole. This
should give you 1 7/16” from center to center of the first 2 holes. This
should give you 4 1/2” from center to center of the two outside holes.
Redrill the left pilot hole to 1/2” Redrill the other 2 pilot holes to
11/32” Then tap the hole with a 3/8-24 Tap. Finish as required.

Cut a piece of the 3/8” Aluminum rod to about 21”. Attach a vice-grip to
one end. Using a 3/8-24 Die cut in about 8 threads in the other end. Screw on
the Coupling Nut that came with the SO239 Mount Tighten as much as you can.
Measure the rod & coupling nut & cut to exactly 19 1/4”

Cut a piece of the 3/8" Aluminum rod to about 59" Cut another piece about 8" Attach a vice-grip to one end. Using a 3/8-24 Die cut in about 15 threads in the other end. repeat for the 8" rod. (If you don't have jam nuts, cut enough threads for 2 nuts & the thickness of the angle bracket.) Screw on one of the Jam nuts & tighten as much as you can. Measure from the bottom of the nut and cut the rod to exactly 57 1/2" Measure from the bottom of the nut and cut the other rod to exactly 6 1/4" (Remember the nut must be included in the Measurement.) (Put a small amount of grease on the threads) Screw the elements into the threaded hole of the angle bracket and tighten. Screw on the other nut and tighten it.
Attach the 19 1/4" element in the 1/2" hole using the rest of the SO239 Mount. Mount & test your new antenna.

SWR should be 1.1:1 at 146 MHz and about 1.2:1 at 144 &148 MHz.

SWR should be 1.1:1 at 443 MHz. and about 1.2:1 at 437 & 450 MHz.

The J146/440 Dual Band with single SO239 feed is only $ 39.
Please add $ 6. Shipping & Handling per order (for US Funds).

Jim, AA2QA wrote:
"The problem, if you run into one, will not likely be the transmitter power, nor the receiver noise factor- it is likely to be obstruction of the path between your receiver and the transmitter."

From a glance at the map Jim is likely right. The obstruction is likely to be from being over the horizon. The reflection point, or more aptly the grazing point is likely to be seawater which often produces deep fades.

I`ve worked with microwave receivers capable of TV relay. Sensitivity was between -80dbm and -90dbm. At UHF and VHF, better noise figures and sensitivities are produced in cheap TV sets. Quoted sensitivities seem rare probably because steady improvements tend to make such figures soon obsolete.

What Terman says about TV reception is more useful: "Television receiving antennas are usually mounted as high as practical above the earth, because the strength of the high-frequency signals from a distant transmitter will be directly proportional to height---. The minimum height necessary to obtain a usable signal will depend on the distance to the transmitter.

Directivity is required in the receiving antenna in order to inrease the capture area, and to provide the possibility of discrimination against undesired transmission paths. When the signal strength is not great the receiving antenna should not only be as high as possible, but should be of a type having a relatively large directive gain."

Best regards, Richard Harrison, KB5WZI

I never put anything on mine, mainly because when we put it up it was
December, there was six inches of snow on the ground, and it was below
zero. It sat through ice storms, rain, and whatever, and never showed any
signs of cracking or deterioration. If there was any change in it's

attentiation characteristics I did not notice it and had a reputation for hearing signals that others locally could not, and also for being heard when the others
weren't. Despite all the things that some "experts" might point out, it worked like crazy
for me. No extra expenses like wax were incurred. Some time after I took it down, I used the line for a "twin-lead" 75m marconi which I have since passed on to someone else -- it is still in use today -- that makes it about 17 years old now! The new owner consistently works world wide DX on 75m with it!

I think MOST everyone misses the point! It is my opinion (based on gutt-instinct and not hard facts) that NC and Fractal Antenna Systems are being evasive intentionally. The purpose, in my opinion, is to raise as much "talk" about the technology and company without showing their "weak" hand as to drum-up someone to make a purchase of company and rights.

It would seem that if NC and FRACTENNA was as good as he/they boast, they would be more forthcoming with information to sustain their assertions.

It is further my opinion that NC was given the "boot" because of one of two things. His grant money ran out or he was found to be spending way too much time on personal business as with the newsgroup and FRACTENNA while on the BU dole.

Of course, all of the above is my constitutionally protected opinion on the matters at hand and could be wrong. No one should draw conclusions from these statements, but rather should use their OWN minds to figure-out the FRACTAL jig-saw puzzle.

I am using a 260 foot end fed zepp. I use 450 ohm ladder line over 200 foot long. I use a heathkit 2060-A tuner with it and it will load a 1:1 on all bands. I works very well on 17 with very little inductance in the the tuner, at 1:1 across the entire band with out retuning. The ideal feed line would be open wire with 6" feeder spreaders. I believe you would be better off going to the 450 ohm line. This is available from Cable X-Perts on a quick delivery basis. Get the 14 ga. if you can. The light stuff doesn't hold up that well. I am not sure but I don't think the 300 ohm radio shack will take a full KW. Ok for transceivers though. I am working on a Sterba Curtain which should be up next spring. This will use the 600 ohm open line with the six inch spreaders (low loss with this). After sixty years as a ham I firmly believe 600 ohm balanced line is the best. Cable X-Perts fone is 1-800-828-3340 orders only. In the 99 catalog the price was .99¢ a foot up to 499 feet.

I think W was referring to self-control, as opposed to state control, in
that increased freedom requires increased responsibility and
accountability. For example, you can't legally yell "Fire" in a theater
without consequences if there is no fire. The exercise of Rights must
be tempered by Responsibility and good judgement.

I am the guy that originally started this thread. Yes, I am in a
townhouse that is kind of a 'T' shaped place with 2 long units making
up the top of the 'T' and 3 smaller units making the bottom element of
the 'T'. I own one of the longer (3 bedroom) units and have maybe
about 50 to 60 feet of attic run (right over the neighbor's unit -
yikes!).
Another option I was thinking of was trying one of those B&K (B&W??)
whips antennas that are advertised to run on 2 through 40 meters that
clamp on an open window with the counterpoise wire you run around the
floor of the room. I was thinking I might even be able to clamp that
thing on my patio fence (about 6 feet tall) and just run outside to
change bands with the counterpoise clamp. That would at least get it
away from the tranciever and reduce some of the RF problems, and also
keep it away from the neighbors as best as possible too.

Of course I think the ideal antenna for my situation would be one of
those AEA Isoloops (or the MFJ clone). I see those on EBay every now
and then, but don't bid agressively enough to win! :-)

Tom KA7VIK - the condo dweller!

I've done that here on ch#57. I used a radio shack UHF TV antenna that I
got half price for 12 bucks. It's about 25 el total. "about 10 reflector
elements in a corner reflector type setup and about 15 log type
elements. Worked ok. A good 70cm beam would be better. MK

You sure don't need to spend 1000's on an all band mobile. I can set one up for 500 bucks. Including a radio.
Maybe less. My current ic-730 I bought about 10 years ago for 450$. All my antennas are pretty much free as I build them from junk. Being I am usually on 40/80 meter mobile, a ten meter rig would be useless for me. The skip zone on tem meters is so long, the only people you will talk to will be far away usually. And if the band is closed it will be useless."This will be all the time nearly in a non solar peak year".I use run more close in. If I break down and buy a new ic-706 like I've been thinking about recently, I'll have a about 900 $ in the new rig. Still not in the 1000's range, and thats for a brand new radio. MK

Source record: 177403

Why not dump mode "J" and move up to mode "L/S" instead? From my
understanding that is going to be the preferred mode for P3D anyway. The
mode "L/S" antennas are so small you could stick them on a cheap camera
tripod, and track the slowly moving satellite, at apogee, by hand. A small
helix antenna for each band would be shorter than your arm. I'm thinking
about doing this myself and see if I can work the bird out of my apartment,
that is IF it ends up in the planed orbit, AND the electronics work as
planed too. I'm waiting to see how things go before I start spending money,
and building stuff however.

If you cause TVI on 40m and 80m excellent it means you are getting some RF out. I have always had problems with TVs and phones on 80m and 40m. The solution is the RSGB ferrite rings. I use one in each of the phone sockets here I wind a quad winding of about 14 turns on the ring and connect that between the incoming cable and the socket terminating point. I normally solder the windings to the incoming wires, you could use a connector if you wish.

On TVs I find most TVs and videos for that matter are cured with a RSGB ferrite ring in the antenna downlead close to the TV. I get small bore 75 Ohm coax (www.maplins.co.uk supply this by the metre) use a free Belling Lee plug and socket (also from Maplin) and use 14 turns. In stubborn cases I also do the same on the mains lead but house it is a small ABS box and use a 13 amp plug and socket along with strain relief grommets on the box.

1459. Tuning a multiband dipole for meteor detection

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-30 22:55:25 UTC
From: Luke Seubert <lseubert@radix.net>
Message-ID: <39FDFBC0.CEDFBCCF@radix.net>
Source record: 177408

Good day,

I am building a multiband dipole antenna designed to detect meteors which I plan to donate to my local astronomy club for educational use.

In brief, this dipole antenna will be designed to tune in the VHF TV video frequencies of Channels 3 and 6, 61.25 and 83.25 MHz respectively. In order to hear the "pings" and "warbles" of passing meteors, one then tunes the receiver to these frequencies using AM or SSB without AGC. (For a more detailed description, please refer to: http://mnbsun.stmarys.ca/~lonc/meteors.html)

My question involves the proper use of an MFJ-259B Antenna Analyzer. I roughly understand how to use one to properly trim and tune a regular dipole. When trimming several dipoles connected to the same feedline, does trimming one dipole effect the tuning of the other dipole in any way? Or can I simply tune each dipole in turn without regard for any effects on the other?

Many thanks for your assistance.

1461. Re: Tuning a multiband dipole for meteor detection

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-30 23:52:32 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39FE09C0.FFC87013@eznec.com>
Source record: 177410

If the antennas are separated a fair amount (by say, 30 degrees or so), the interaction will be minimal. Whatever interaction there is will be primarily the longer dipole affecting the shorter one, so you should tune the longer one first. If the dipoles are parallel or nearly parallel, the interaction will be strong. Again, though, the majority of the interaction will be the longer one affecting the shorter one, so again you should adjust the longer one first. But with parallel or near parallel dipoles you might have to go back and readjust the longer one also, and make more than one iteration of the process. You'll also find that tuning will be quite critical, and will result in unexpected wire lengths. Parallel or near parallel dipoles are also quite narrowbanded, but that probably won't be an important consideration in your application.

Snip off the end of the cable with the plug.

Heat up your soldering iron and removed the old cabling from the plug.

Re-install, re-solder the plug to the remaining cable, and make sure
there is no short between the center connector and the outer braid.
(If you get things too hot, the outer braid can pass right through the
plastic filler and contact the center conductor.)

Hi Barry--

My bet is Chip is still happily employed by BU-Metro and will remain so (easy enough to confirm). He'd have to commit social mayhem to be "terminated" or de-funded mid-semester. It just doesn't happen in academia. Makes no sense.

IMHO, it's more plausible he was "conveniently terminated" from FAS by his own family or board to protect assets from legal exposure caused by escapades on here. First, they return the copywrites, then pull his "official status" to protect the family jewels. This feigned act of "rejection" works for Chip. Besides protecting family assets, it also lends pathos to his bogus complaints against Roy and others. Kinda like dressing up the plaintiff in a cast and a crutch before tiral (an old lawyers trick). Phil's done nothing to disconfirm this scenario by his huffing and posturing, has he?

Of course, this is only an idle opinion and I freely admit I could be very wrong. But, vicious threats accompanied by no specifics always invite speculation over darker motives.

I agree with Rick.

After seeing all the false claims and sympathy gathering ploys over
the past few years, I certainly wouldn't trust any statement made by
anyone at that source.

This is probably another attention gathering scheme, to keep the lime
light shining. You guys are probably just getting trolled.

It amazes me that 80% of the traffic here surrounds Cohen and his
nonsense.

Easy enough to find out; if Chip is no longer 2 out of 3 officers of the
company, a change will have to be filed with the state of Florida and that
info is publicly available on the web....

Judd,
There's no 'easy' way to do this, it requires quite a bit
of engineering, or modification to make it work. The winch
operated telescoping masts, and some of the telescoping towers
use the same system, a series of pullys and one continuous
cable. Your drawings are probably the same as those I've seen,
but if you'd like I could probably make a very simple diagram
for you.

Picture the mast as follows:

Section one, largest diameter, is fixed to foundation and forms the lowest section
Section two, telescopes within section one, and forms middle section
Section three, telescopes within section two, and forms upper most section.

Two pulleys and two cables are required at a minimum.

Sections one and two each have a pulley affixed near their tops.

A winch fastened to side of section one lifts bottom of section two via a cable through the pulley atop of section one.

A second cable is attached to top of section one, passes through pulley on top of section two and is attached to bottom of section three.

The action of raising section two, is transferred through the second cable and lifts section three.

Sufficient clearance is required between the telescoping tubes to accomodate the cables and pulley sheaves.

Cable working strength, loads and stresses are another matter for which I offer no liability. Keep fingers and other limbs out of the works at all times.

resistance. Mr.
> Best has discovered for himself that the SLA will not only predict the rad
> resistance incorrectly, but similar values of rad resistance are obtained
with
> radically different values of enclosed area;

The statement above ..

"Best has discovered for himself that the SLA will not
only predict the rad resistance incorrectly, but similar values of rad
resistance are obtained with radically different values of enclosed area"

.. does not apply to any aspect of my analysis as in all cases, the loops I
modeled had virtually identical physical aperture (enclosed area) and very
close, if not identical, total wire length. My analysis of the MI2 and
non-fractal loops did not consider variations in loop aperture size with a
comparison of radiation resistance.

Additionally, the Small Loop Approximation (SLA) in the context under which
it was written is not incorrect. It simply should not be taken out of
context. The SLA is used to describe the behavior of small circular loops
where the current distribution is assumed to be constant (uniform) over the
loop structure. In the SLA model, it is assumed that the circular loop
radius is less than approximately 0.05 wavelengths. Since the loop must
remain circular as its diameter decreases, the total wire length in the loop
is also decreasing as diameter decreases. As a result, the smaller the loop
becomes, the shorter the overall wire length and the radiation resistance
decreases to a point where eventually, the loop is small enough such that
the loss resistance is greater than the radiation resistance and the loop
has lower efficiency. In the SLA model discussion, it is clearly stated
that if the loop geometry changes to a point where the current distribution
is no longer uniform, a more complex analysis method is needed (like
numerical modeling) to describe the loop properties. From Balanis (1982):
"The most attractive polygonal loop antennas are the square, rectangular,
triangular and rhombic. .. because of their more complex structure,
theoretical analyses seems to be unsuccessful [RWP King - 1956]." Kraus and
others recognized long ago that the SLA model would not be a valid tool to

accurately "model" complex loop structures, which would include fractal loops.

Another way to look at the SLA is the following: keep the loop aperture and total wire length constant and continually reduce the operating frequency and examine the radiation resistance. A circular loop and a fractal loop will exhibit similar behavior. As the frequency decreases (aperture area and wire length decrease wrt wavelength) the radiation resistance will decrease and eventually, the wavelength will be sufficiently large, such that the loop is small, and the loop will have lower efficiency.

Clearly, with a complex loop geometry, the SLA formulas cannot be used to directly
determine the actual radiation resistance but the concepts of the SLA remain valid. To state that the radiation resistance has nothing to do with the area of a loop (fractal or otherwise) is simply incorrect. A fractal loop 1/2 the size of another fractal loop of the same geometry would not have the
same radiation resistance at the same frequency. The radiation resistance of any loop is a function of numerous factors, which include the area of the loop, the total length of wire in the loop, the feedpoint location and to a lesser extent, the loop geometry.

>
> 2) A fractal loop has a much higher radiation resistance, in this case
> attribuatble to the two current maxima.
>

A square, non-fractal resonant loop has two current maxima as well, so this is
not a unique characteristic of fractal antennas.

I must have missed the earlier suggestions so if I'm missing the point forgive me. But, have you considered using coax and not having all of the fuss required to properly use balanced line?

I gather that your line will be less than 100' long and unless you have your dipole up 100' or so, the feedpoint Z will be reasonable for direct coax feed.

> losses (e.g. - poor radiation efficiency)?

Exactly!

To demonstrate this to a CB friend, I built him a base-
loaded three foot whip. The radiator was 3/16 brass rod,
silver plated, and the large base coil was 14 gauge silver-plated.
An L-network was combined with the loading coil for
impedance matching by adding an air variable from the coil
input to ground.

Bandwidth, as predicted for this length antenna, was a
slightly over 20 kHz for a 2:1 or less VSWR. Tuning was a
real pain as standing within a few feet of the antenna
detuned it drastically, but after many hours of iterative
tuning (trial and error) we finally got it adjusted for
27.185 - CB Channel 19.

To test the antenna, we did A-B-C testing against a bumper-
mount quarter-wave whip and a commercial 45" center-loaded
CB antenna. About 30 tests were run with other stations
comparing the signal strengths of the three antennas.

The results were pretty much as expected. The quarter-wave
bumper mount antenna gave the highest signal strengths. The
homebrew antenna, on Channel 19, performed almost as well
with most contacts reporting negligible differences between
it and the full sized whip. The commercial antenna always
produced one to two S-units lower signal strengths. On one
channel on either side of 19, the homebrew antenna did a
little worse than on 19, but it still outperformed the
commercial antenna by far. However, the VSWR two channels
away made it unusuable on these channels. On the road

testing confirmed its good performance - until a truck passed in an adjacent lane and detuned the antenna again!

There is a reason commercial CB antennas use stainless steel whips - the added RF loss. Some CB antennas even have stainless loading coils or extremely fine wire to increase the RF losses further still. The reason - to trade efficciency for bandwidth.

And before anyone suggests the matching network limited the homebrew antenna's bandwidth, it should be noted that an L-network provides impedance matching while providing the least bandwidth reduction.

Hi George,
I guess I should have reiterated more when I posted but I belong to a two-ham two-wide-body driver family namely xyl (of 41yrs) -KD6QCH. We also have a very serious dual computer/ham radio console that only one of us uses while underway. The driver can't even see the GPS/Street Atlas 8.0 (SA) laptop we use for navigation; only the co-pilot can. The driver can however hear the SA turning instructions that are broadcasted on the stereo system. I'll attach a jpg in a couple days after I reinstall some packet/tnc wiring.
I do have a couple Hustlers for stationary use that hinge down while underway. Also been thinking about the radial less R-7000/R-8000 mounted on the ground for stationary operation even in roadside parking areas.
The problem with the Hustlers I don't have the good luck you are having with matching. Very high SWR even barefoot then impossible with the linear causing arching, etc. I even have straps from Hustler base to bumper supports with no improvement. I've tried everything except trying to temporarily ground the motorhome with a earth rod. (hihi)
I guess I don't understand the capacitance to ground concept you speak of. I seem to be getting the best luck with the MFJ ground counterpoise unit but SWR isn't good.
I started this post because I happened to remember some of the older (preset) larger aircraft that simply had dipoles on the under bellies that I could maybe duplicate (at 40 feet each) and tune with SGC or ALINCO type units (?). What about that? And what would I gain if anything besides low wind resistance?

> impedance referred ?
>
> Is it the impedance looking into the 2-wire line ?

Yep, it is the impedance seen when feeding a 50 ohm dipole with
about 0.73 WL of 450 ohm ladder-line, a relatively common occurence.
This would happen when a 20m dipole is fed with 46ft of ladder-line.

Assuming typical ladder-line may have an SWR ranging up to 20:1, the
poor balun may be required to handle 9000 ohms, an almost impossible
task. That's why I make sure my balun/choke see a current maximum
point.

1492. Six Challenge Winning Brooms

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-31 06:38:39 UTC
From: Richard Clark <rwclark@rwclark.seanet.com>
Message-ID: <sF=+OZgA9xTxQgS8+d6jZ146vgGl@4ax.com>
Source record: 177341

Hi All,

Don't hold your breaths waiting for the ink to dry on that
check, these are the winning designs of the
rec.radio.amateur.antenna Fractal Antenna Challenge
which can be found at
http://www.seanet.com/~rwclark/antenna/fractal/Fractal%20Challenge%20Winner.htm

In a nutshell the results were:
VE9SRB Random2 First Place [Challenge FOM = 4.155]
VE9SRB Random3 Second Place [Challenge FOM = 4.122]
VE9SRB Random4 Third Place [Challenge FOM = 3.968]
VE9SRB Random5 Fourth Place [Challenge FOM = 3.682]
VE9SRB MI2 Fifth Place [Challenge FOM = 2.009]
VE9SRB Random1 Sixth Place [Challenge FOM = 1.005]
n1ir MI2 [Challenge FOM = 1.000]

All designs had to be adjusted in some manner to resonate at
the specified frequency of 14.15 MHz. All antennas were
judged to be "about" 1/8 wavelength dimension on each side
of the antenna. As NONE were at, or under, that spec. I
normalized FOM's to the n1ir MI2 design (all 6 other designs
took a scoring hit).

Other issues drove me to make subtle changes (like one wire
table with 550 segments - come on now!). Such twiddling may
shift the line-up at the bottom of the pack - but the
leaders are clear. In any event, having introduced some
error, no matter how slight, I make all designs available at
http://www.seanet.com/~rwclark/antenna/fractal/Fractal%20Challenge%20Winner.htm
upon approval.

True (though not quite literally ;-)

>They
>didn't just destroy the nuts and bolts, they burned mills down

That's also true.

>and
>killed people.

In the course of the riots, people were killed, but mostly soldiers - the only ones who had firearms. In case anyone gets a mistaken impression, the Luddite riots were nothing like the modern terrorist killing of other "civilians".

>Their agenda also included a belief that
>indudtrialization would destroy society.

That's a very 20th/21st-century educated way of putting it. The people involved at the time had much more immediate motivations like the disappearance of their own jobs... and events proved them right.

Also, the picture was very complex. The riots actually occurred in two waves, and in a number of places that were essentially isolated. There was not a single "Luddite" movement, and their leader "General Ned Ludd" did not even exist.

I'm not trying to pick an argument with Brian, but only to point out that the modern meaning of "Luddite" as "anti-technology" has very little to do with what actually happened in northern England in 1811-1816.

In the present discussion, it would be better not to use the word at all.

Cecil, I don't see what you have to worry about.

With a choke balun there's just a pair of short wires between one end and the other. It has the effect only of increasing the length of the main transmission line by the length of the line wound on the balun. Otherwise the balun has no effect on normal line operation.

The effectiveness of the choke, considered as a single conductor wound round a ferrite core, depends only on the input impedance of the transmission line also considered as single conductor (2 wires in parallel). Which is an entirely different impedance. If it has a very high impedance so that the choke has no effect then you don't need the choke anyway.

I again repeat my offer to send gif files of a N3's MI2 installation and his SWR plot.
This is not a model but an actual installation.

The best SWR he gets is about 1.2:1 and I believe most, of not all, of the 10M band has less than a 2:1 SWR.

This is one of many MI2 designs which have excellent 50 ohm match.

Please query at chipn1ir@aol.com soon, because I send these out at one time and already have many requests.

Bob wrote:
"---Channel 2 transmits from more than 3,000 feet up on Mount Seymour, near Vancouver,"

That mountain is appropriately named. Its height is significant. The distance to the radio horizon in miles is approximately the square root of twice the antenna elevation in feet. From a height of 3000 feet the radio horizon is about 77.5 miles. If the total distance to the receiver is 140 miles, you need enough receiving antenna height to see the horizon 62.5 miles away as a minimum. That height calculates as 1953 feet. That`s lots of sections of TV mast.

We had figured 2450 feet on each end of the path with equal heights. Having 3000 feet on the transmitter end reduces the required height to 1953 feet for the receiving antenna.

That is puzzling, indeed. My newsreader is configured to supply
w1rfi@arrl.net as my reply address. I just sent email to w1rfi@arrl.net and
got a failed mail message. For some reason that is not apparent when I look
on the ARRL members-only page, the system thinks it should send the email to
3Dw1rfi@arrl.org. That is NOT a valid address, so I would expect it would
fail. I have reported this to our IS folks.

I can be reached at:

w1rfi@arrl.org
w1rfi@aol.com

If Richard wants to send me his email that criticizing spelling errors is in
poor taste on newsgroups, he can use either of those two addresses.

Others here have told me that coax or coax/balun will not broadband as
well as twinlead. My current antenna is approx. 240ft.+ random up about 40ft.
and I'm using a MFJ 941-E to tune. This does very well for 17 and 12 in
particular. Fine for 10 and 20. But the bottom drops out when I go to 40/80/160.
Especially 80/160. The antenna that's being proposed would be 264ft. Dipole
up about 50-60ft. and roughly bent to an open "C" shape. Feedline length would
be around, say, 40ft. vertical down and addt'l 30 or so feet to shack. If you're
interested, rig is FT-980 with 100W peak. No plans for linear at this time. If
you've any thoughts you'd like to contribute I'd welcome them.

The purpose of a choke is to reduce common-mode currents.
If the choke has no effect then it is not reducing common-
mode currents. The result is all the problems associated
with common-mode currents, e.g. RF-in-the-shack, feedline
radiation, TVI, etc.

> This would happen when a 20m dipole is fed with 46ft of ladder-line.

This particular case isn't so bad. The antenna is center fed with a balanced transmission line and may not even need a balun at the feedpoint.

Providing a longitudinal (common mode) impedance of a couple of hundred ohms will likely provide all the decoupling you need since in this particular case, the common mode impedance of the antenna feedpoint is probably less than 50 ohms. The differential mode impedance of the balun should be somewhere between 50 and 450 ohms which is very easily achieved with a bifilar winding made from twisted pair.

The situation on 75 meters would be terrible however. First of all, even ignoring the balun problem, the antenna is too short to work well on 75 meters unless it is very carefully designed for the specific situation and even then, will be touchy to tune. The feedpoint impedance might be in the neighborhood of 10 - j1500 ohms resulting in an SWR on the 450 ohm feeder of 545:1. Depending on the core used, a typical balun might have a differential mode capacitance of 100 pF. The differential mode inductive reactance of the balun is negligible on 75m. Adding the 100 pF capacitance in shunt with the antenna feedpoint transforms the feedpoint impedance from the original 10 - j1500 to the considerably worse value of 1.5 - j581 ohms (SWR = 800:1), and results in significantly increased transmission line losses due to the lower resistive component. In order to transfer 100 watts into the antenna feedpoint, a current of 12.2 amps is required and results in a feedpoint voltage of 7117 volts!

Not only will the balun likely arc over on 75m, it won't provide significant common mode decoupling.

Barry, WA4VZQ wrote:
"There is a reason commercial CB antennas use stainless steel whips- the added RF loss."

I think the whips are stainless steel for mechanical reasons. Electrically shallow current penetration makes resistivity more significant as frequency rises. But, the r-f resistance of a CB 1/4-wave whip is still small. It varies with diameter and resistivity.

A 1-inch diameter copper surface has a resistance of 0.001 ohm per foot at 1 MHz. Rough scaling that for a 1/4-wave stainless steel whip adjusted for the resistivity of stainless steel at 30 MHz gives a resistance of about 0.3 ohms per foot. Current varies from maximum at the drive point to zero at the tip of the whip, etc. but I am only trying to find a ballpark value.

So, if our 9-foot whip has 2.7 ohms of r-f resistance, and it has more than 10 times that value of radiation resistance, the loss resistance is almost negligible.

If the above were not true, there would be a big market for plated antennas. There isn`t!

Hi All,

With permissions granted, I have made those EZNEC files available (the originals) and added screen shots of the antennas themselves to my web page that follows. They are quite an assembly of twisted wire and it is instructive that the best antennas are not always those found in text books.

http://www.seanet.com/~rwclark/antenna/fractal/Fractal%20Challenge%20Winner.htm

In a nutshell the results were:
VE9SRB Random2 First Place [Challenge FOM = 4.155]
VE9SRB Random3 Second Place [Challenge FOM = 4.122]
VE9SRB Random4 Third Place [Challenge FOM = 3.968]
VE9SRB Random5 Fourth Place [Challenge FOM = 3.682]
VE9SRB MI2 Fifth Place [Challenge FOM = 2.009]
VE9SRB Random1 Sixth Place [Challenge FOM = 1.005]
n1ir MI2 [Challenge FOM = 1.000]

All designs had to be adjusted in some manner to resonate at the specified frequency of 14.15 MHz. All antennas were judged to be "about" 1/8 wavelength dimension on each side of the antenna. As NONE were at, or under, that spec. I normalized FOM's to the n1ir MI2 design (all 6 other designs took a scoring hit).

Other issues drove me to make subtle changes (like one wire table with 550 segments - come on now!). Such twiddling may shift the line-up at the bottom of the pack - but the leaders are clear. In any event, having introduced some error, no matter how slight, I make all designs available at http://www.seanet.com/~rwclark/antenna/fractal/Fractal%20Challenge%20Winner.htm with approval.

Andrew,

Here is my problem. The subject of the thread is "160m dipole....".

What I see above is discussion on 10, 12, 17, 20, 40, 80, etc.

If this is a 160 meter only dipole, then I recommend coax feed. If it is to be used on other bands as well, then a balanced line/balun/tuner is one option. Another is a parallel dipole, a trap dipole, or a combination of the two, option.

In any event, I would not recommend the 300 ohm line but something more substantial such as Wireman's so-called 450 ohm stuff.

Fortunately, you have enough length that operation on 160 is not compromised too much, although if you are going to use this on all bands, the pattern is going to be a mess.

73,

Wes

Since openwire is pennies per foot, why not just order some? You won't find it all that much cheaper at a hamfest.

What is "bottom drops out?" Can't tune the SWR down or receive signals are weak? I've stayed away from unbalanced antennas, so I'm certainly without direct knowledge - but I read that for the lower bands the importance of grounding becomes all the more significant and is critical to effective 160M radiation. Just what I've read, mind you.

It is my opinion that Kraus's work re: the Small Loop Approximation is being taken out of the intended context and used inappropriately in the discussion of
fractal loop antennas.

Kraus's discussion begins with the straight-forward circular loop. He discusses the situation where the loop is small with respect to the operating wavelength. He clearly states that the circular loop radius is "<< wavelength". In this case, he assumes that since the loop is electrically small, the current distribution on the loop is essentially uniform. He then goes on to develop "approximations" for describing the properties of the electrically small loop antenna with uniform current distribution. There is nothing incorrect about Kraus' analysis or conclusions in this context.

As for the shape of the loop, he also addresses the issue of a square loop, where again it is assumed that the loop is electrically small and has a uniform current distribution. He specifically defines electrically small to be the situation where the enclosed loop area is less than (wavelength^2 / 100). He states that "as a generalization, we may say that the properties depend only on the area and that the shape of the loop has no effect when the loop is small. However, this is not the case when the loop is large." Clearly, Kraus recognizes that this is a generalization for electrically small loops and that it does not apply for large loops or for loops where the current distribution in not uniform.

To make a statement as follows ...

"the Small Loop Approximation (see, for example Kraus's ANTENNAS) , which ascribes the rad resistance to the enclosed area of the loop, is INCORRECT;
in fact, the area of the loop has nothing to do with the radiation resistance."

... is, in my opinion, technically incorrect and an unfair characterization of Kraus's work for two reasons:

1) Kraus's statement that the antenna properties depend only on the loop area are clearly made in the
context of a discussion of electrically small loops with uniform current distribution. Kraus would and has recognized that this statement would not apply to large loops or to loops with non-uniform current distributions.

2) The fact of the matter is that in most cases, the
area of a loop does impact the radiation resistance of the loop. A fractal

loop antenna of area X, would not have the same radiation resistance of a fractal loop antenna of area X/2, where both have the same geometry basis and the resistance is determined at the same frequency. We must recognize that as loop area changes, the total wire length changes as well since the geometric shape is scaled.

The MI2 fractal loop antenna and the other "random" or arbitrary antennas we have been discussing have a physical aperture of 2.8 m by 2.66 m for a total enclosed loop area of 7.45 m^2. The resonant frequency of these antennas as modeled by EZNEC varies slightly but is typically around 15 MHz. In the case of the MI2 as I modeled it, the resonant frequency is about 15.155 MHz. Using Kraus's formula for the definition of a small loop, the loop area would have to be less than 3.91 m^2 to be considered "small'. The MI2 loop and the other antennas we have been discussing are not electrically small antennas. Additionally, based on the EZNEC analysis, all of the antennas we have been discussing have two current maxima, so they do not have uniform current distribution. To relate Kraus's discussion of small loops with uniform current distribution to these antennas and then declare his work to be "incorrect" is clearly inappropriate since neither condition exists with these antennas.

Now from the other perspective, let's consider the case where the MI2 fractal loop antenna is small with respect to the operating wavelength. With the MI2 as I modeled it, the resonant frequency is approximately 15.155 MHz. At this frequency, the antenna current distribution has two maxima and therefore, the current distribution in not uniform. At a frequency of 10 MHz, the antenna no longer has two distinct current maxima and the current distribution is starting to become more uniform over the loop structure. At this frequency, the loop is still not "small" according to Kraus's definition. At a frequency of 4 MHz, the antenna current distribution on the MI2 is now uniform and exhibits no maxima. The loop is "small" according to Kraus's definition which would require the loop to have an enclosed area
less than 55 m^2. Although I have not checked to see if there any segment problems in the EZNEC model, it appears that as the fractal loop gets smaller with respect to the wavelength, the current distribution does become more uniform as Kraus assumes. Additionally, the radiation resistance does change with aperture size (area) as Kraus indicates. In fact, at this enclosed area
size, the approximate radiation resistance of the MI2 at 4 MHz, predicted using Kraus' formula is about 0.055 ohms. EZNEC calculates it to be 0.067 ohms. The
efficiency of the MI2 loop at this frequency is approximately 3%. The predicted gain is approximately -13.8 dBi. Kraus's "approximation" isn't so "incorrect"
after all.

In general, the radiation resistance of any loop is a function of numerous characteristics, which include the total enclosed area, the total wire length in the loop, the feedpoint location and the loop geometry. None of this contradicts Kraus's small loop "approximation".

Hi,

I currently tow a Jeep behind my Pace Arrow. I use a High Sierra screwdriver on the Jeep, and love it. I plan on getting a second mount and perhaps and extension mast for the RV. It is an easy swapable mount, should take less than a minute to remove or replace.

I agree that dial spinning and knob tweeking is a bad thing while driving. I like to keep my 706 tuned to one of the marine mobile nets or one of the traveling nets, ie. 14.300, MICARS or EACARS while driving. I check in and chat on occasion from the Jeep.

Answer: No problem receive. Can achieve reasonable SWR on tune-up
(say 2:1) but in reality, ERP is down 50% or more and based on signal reports
I'm clearly just not putting out much of a signal. As you probably know, a
FT-980 will power down if too much is bouncing back into it. It is my
understanding that the best cure for this is to put up a more balanced antenna
that will in turn put a better signal out. Remember that MFJ is showing 2:1 on
a cross-needle display and you could technically have those needles pointing
way up and still get " 2:1 " but you'd be putting out peanuts. Leastwise that's
my best understanding of it. You also state, "why not just order some?" Well,
that was kinda what I was asking. Other respondents didn't seem to think it
would really make much of a diff. If you feel differently I'd be happy to hear
what you've got to say.

Egad, Mark, I've personally asked Chip for substantive fractal antenna information, and complained that links in his postings claiming to be to serious information always lead me to smoke and mirrors (or even less than that). I've never been able to get such info. I love learing about new things, but get more than a bit discouraged when nothing to help me with the learning is ever offered--belay that--delivered. I could only laugh when Chip claimed that HP Journal was as uninformative as the FAS website was. That one wasn't even worthy of further comment, and at that point I gave up all hope of getting any information that would actually let me evaluate fractal antenna ideas through Chip.

Cheers,
Tom

reports

It would probably have to be more than 50%. A 50% reduction in radiated
signal would be 3 dB. This is 1/2 S unit, and it would be somewhat
difficult to tell that from signal reports.

Some rigs will start to reduce power at 2:1 SWR, so you may want to look at
the measured forward power. You can operate any feed line, including
coaxial cable, at a 2:1 SWR without excessive loss (maybe really long runs
of RG-58 or medium size runs of RG-174 would be unacceptable at 2:1 on HF).
Perhaps you could best solve your problem with an antenna tuner.

Cecil, W6RCA wrote:
"True for 10m, but the situation is completely different for a 9-foot whip used with a base autotuner on 75m where the radiation resistance is more like 1/10 the RF resistance."

It`s true that the 9-ft whip radiation resistance is probably between 0.4 ohm and 1 ohm, depending on current distribution. The 9-ft whip is 90 degrees at 27 MHz (and a few more degrees at 10 meters) but it is only about 13 degrees at 4 MHz (and a few less at 75 meters). So, loss resistance dissipates a corresponding fraction of power as its fraction of the total resistance dictates. An offsetting improvement occurs with the lowered frequency. Skin depth increases and this lowers the resistance which dissipated power in the whip.

A more serious problem may arise from loss in the autotuner`s loading coil. This was not needed when using the whip at 10 or 11 meters.

Best regards, Richard Harrison, KB5WZI

> Jeff VE7GMX

Unless the older rig is the absolute simplest rig you will not get
a direct operating frequency reading from the Heathkit IM-2410.
If the rig has 1 or more local oscillators, which most SSB rigs
have, the counter will only show the oscillator you are monitoring.
In most cases there is only one oscillator for tuning and any
others are crystal controlled.

Roger, K6XQ, made a great recomendation with http://www.aade.com/
but if you want to keep with older equipment, Heath in particular,
you need to be looking for a SB-650. The SB-650 is capable of
counting and adding/subtracting multiple oscillators and is
made for adding on to almost any old rig. The problem you will
have is finding one. I bought a working one at a hamfest in
Northern Arizona for $65.00. An even bigger problem to finding
one, is finding one that works. The unit uses Nixie tubes and
replacements, althought available, are expensive.

My recomendation is to go with http://www.aade.com/". You will
need to determine if the rig is single or dual conversion, so
you can select the correct display.

>

My only experience with trap failure was with an old Mosley TA33 tribander years ago. I bought it knowing it had some problems and took the traps apart before attempting to use it. Turns out that the defective traps were filled up with spider webs which had became damp from humidity in the air and caused the traps to arc, burning some of the plastic coil form inside the traps. Evidently the carbon path changes the operation of the traps.
The spiders which work their way into the weep holes in the bottom of the traps float in the air on a long string of their web material as they migrate each fall, and can get caught on your beam, them find their way inside the traps.
The only thing you can do is disassemble the traps and determine what you need to do to restore them. Hopefully replacement parts will be available from the manufacturer as they were for the TA33. If not you can always attempt to fabricate your own.

I have a cardboard slide rule that does that and more. My father-in-law, W1DBM, gave it to me years ago as evidenced by the $2.00 price printed right on its face. It is the "L / C / F Calulator Type A" from ARRL. It works fine and no batteries required. But, Reg`s price and delivery are certain to be better.

Hello,
I just received the new sale flyer from Radio Shack and noticed an antenna analyzer on sale for $199.95 that looks exactly like the MFJ-259b. It has the Vectronics brand name and is Radio Shack item #9400683.
I wondered if anyone has used the Vectronics unit and could verify if it has the same features as the 259b? I had no luck finding a manual to download for this unit on radioshack.com.
I have been waiting to get an analyzer, but at this price I just may have an early Christmas present.
All replys appreciated.

Hi all,

My name is Alex Wiecek VE3GOP, and I'm a member of the Polish Amateur Radio Club VE3XPL here in Toronto. We are currently trying to establish a listing of all polish speaking Canadian Ham Radio Operators living either in Canada or abroad. The purpose of this activity is to present a petition to the Industry Canada to obtain a temporary special event callsign to commemorate the 75th aniversary of the Polish Ham Radio Society in Poland. We tried contacting the IC office in Ottawa but they don't seem to be responsive and as such, we have decided that the next approach would be to present them with as many e-mail petitions as possible to make our voices heard.

We need your help, if you are a polish speaking amateur or know someone who is, we would like to hear from you.

Please contact me at alexwiecek@home.com, and if you'd like to learn more about our club, please visit
http://web.ionsys.com/~magnum/ve3xpl/index.htm

your help would be greatly appreciated.

Thank you.

73's Alex VE3GOP

Not entirely. Stainless also offers corrosion resistance. See the numbers
below for the shorter whips like I was talking about.

> Electrically shallow current penetration makes resistivity more
> significant as frequency rises. But, the r-f resistance of a CB 1/4-wave
> whip is still small. It varies with diameter and resistivity.

Remember I was talking about a short, base-loaded whip, like most CB
antennas for trunk or roof mount.

> A 1-inch diameter copper surface has a resistance of 0.001 ohm per foot
> at 1 MHz. Rough scaling that for a 1/4-wave stainless steel whip

> trying to find a ballpark value.
>
> So, if our 9-foot whip has 2.7 ohms of r-f resistance, and it has more
> than 10 times that value of radiation resistance, the loss resistance is
> almost negligible.

But consider the base-loaded 3 foot CB whip has a radiation resistance of
about 2.5 ohms. An extra ohm of loss makes a big difference here. The
same antenna will have a capacitive reactance of about 440 ohms. Also note
the permeability of most stainless steels is greater than unity, decreasing
the skin depth and increasing their RF resistance.

> If the above were not true, there would be a big market for plated
> antennas. There isn`t!

Actually there are copper plated, stainless whips available. But they are
hardly worth it until the antenna resistance is quite low - such as the
lower H.F. frequencies with reasonably sized whips.

: hopefully get a detailed description of the broadcast services offered.
: -art clemons-

Radio Shack (and others) sell small WWVB (60kHz) "Atomic Clocks" which receive the WWVB signal late in the evening here in South Florida.

The clocks that have a seperate "antenna" (on a short cable) actually have the 60kHz receiver in the "antenna" blob. I recently bought a discontinued radio shack clock for ~$15 that is set up this way.

Do a search on "Atomic clocks" for information. I found the blob info on a site where people are recording earthquake tremors and needed an acurate clock. The site tells which wire in the cable does what.

I have a HP VLF Receiver that uses a tuned loop with a pair of 6CW4 Nuvisors AND a **VERY** narrow Collins (10Hz if I remember correctly) Mechanical filter in the base. Later revisions of the loop use FETs and no real filtering in the antenna itself.

The "receiver" portion consists of several 6CW4 TRF stages for a total antenna to detector gain of ~120dB (at 60 kHz)!! They recommend that the antenna be mounted at least 35' away from the receiver to prevent feedback (and they are right ;)

Until WWVB raised their power, even all that gain that wasn't enough to receive a good signal in South Florida. Now it's no problemo.

Source record: 177240

If the common mode impedance looking into the line is very
high there are hardly any common-mode currents to be
reduced. The choke is surplus to requirements.

This can be checked by grounding a centre-tap of the line
and measuring the line and measuring the very small current
which flows to ground. The current will be small because the
source impedance is so high.

If the current is appreciable then the common mode impedance
cannot be so high as you think it is.

Dick Carroll (dixie@townsqr.com) wrote:
[nip]

: Someone here has missed the point completely. The problem with Chip et
: al is not that he has invented new technology which has been rejected by
: ANYONE on this NG, rather that he has consistantly and almost completely
: stonewalled against any and everyone here who has asked for real, hard
: information about his supposed invention.

If the antenna is that great, we would see them being used and talked
about in various radio/technical mags.

; He repeatedly and very
: petulantly insists on directing all who ask to the most obscure of
: scientific writings which are mostly meaningless in deciphering any hard
: information on fractal shaped antennas as any improvement whatever over
: other shapes. He insists that the scientific literature supports his
: claims but so far has totally resisted any and all efforts to get him to
: tell us -right here- how and why.

Ego-stroking comes in different forms.

: It seems more than clear that when he can't or won't divulge, and
: almost all other respected and accepted antenna authorities fail to find
: any such attributes using the scientific references he quotes and their
: own scientific investigation, that his claims are vaporous at best, and
: a virtual scam attemp at worst.

: If he was a serious scientist he would be more than pleased to make
: full disclosure, and we know that if his claims were valid it wouldn't
: be that hard to do.

A simple dBi number would be a start.

: Do I believe that fractal shaped antennas work? Of course- most any
: shape antenna will work.That's not the point of contention. Whether or
: not there is any advantage to those shapes-as is apparntly claimed by
: his writings and attempts to claim patents and copyrights- is the
: contentious area.

From the little I looked into it, it seems that the antenna would be
smaller than similar ("normal") antennas. Sort of like the old "Dyna
plate" ground plate for small boats. (Or taking a 160m dipole, balling it
up and saying "I've got a 160m antenna here".)

: From here it looks like an attempt to force his claims onto the rest
: of the world, like it or not, by mostly bafflegab, bluster and threats

: of lawsuit.

One has to wonder why he would bother to try to convince Amateur Radio operators that his antenna is.... whatever it is he's been trying to prove. He should be too busy making the things for commercial users.

Please note that I for one, will NOT be sending any email to what's-his-name.

I think switching to a balanced antenna would help quite a bit. A 240 ft wire is pretty long even for 40/80 meters but you have a few problems with isolating the feedline, and avoiding excess loss in the tuner. Also the pattern is likely to be fairly random. I've tried a few random wires in my time, and except for high band use as a long wire, I've never had any real luck with them. At least compared to a normal dipole. And rf problems in the shack too. I think in your case being you want all band use, if using the same wire, I'd split it down the middle and feed with 450 ohm line as a 160 dipole if you want 160 meters included. If you only run 80-10, I'd only use 120-130 ft and run a 80 dipole. The reason being is I think it would perform better on 40m as two half waves in phase rather than two full waves in phase. The higher band use should be ok. I'd expect 12 and 10m to be a bit low in performance but thats normal with a 80m dipole on 10m. It will still work. But with a 80 dipole fed with 450 line , 80,40,30,20 would be good. 17 and 15 should be ok also. Myself I run parallel dipoles 160,80,40 fed with coax. But not for the faint of heart. It's 440 ft of wire in the air. Looks like a big skinny legged bug in the air. But I do have the advantage of no tuner or the losses involved. Also instant bandswitching. I use a 989c to tune to other bands if needed. Works ok usually. 30m real good. 20 not so good. 17 ok, 15 good, 12 and 10 ok. But I also have a 1/2 vertical for 10m. I know some like the random wires, but I've just never had that good a luck. I have seen long wires work well on the high bands though, much as you see there. BTW, the 300 ohm line will work ok, but I'd go ahead and get the 450 ohm line. It's quite a bit better. Also I get the thick gauge stuff for lower loss and strength. It's not really the impedance, but the thickness of the wires and covering or lack of it that makes the difference. The impedance is just determined by the spacing of the wires. The wider the higher. It's easier to avoid wx effects with a wider spacing so most end up using a higher impedance line. It's not that anything is magic about 450 ohms. MK

Yep, I know. As far as my end, I think the guy just read my posts from
this weekend and came to the conclusion that all this is just a game to
heckle poor old frac over his "newfound technology". Actually, thats
about the farthest from the truth. I've never really gave much comment
in the past on the merits of the fractel antenna. I have my own opinions
but I pretty much kept them to myself. I thought I'd just let the chips
fall where they may. The only reason I jump on him is his constant BS,
threat of lawsuits,whining, etc. I've always been open to new ideas,
good or not. But being this is an open forum I expect new ideas to get a
good grilling over before being excepted as fact. It seems when it comes
to fractel antennas no one is ever correct except fracky.
That, coupled with his huge library of usable data, "NOT!" would make
anyone suspicious. The only real usable data of any extent seems to be
on Richard Clarks website. Of course, that chaps fracky to no end.

That's the problem - the common mode impedance is much less than
the load impedance.

The current on the coax center conductor is matched by a differential
current on the inside of the coax braid. At the coax to balanced line
junction, the current can flow into the balanced line *OR* down the
outside of the braid. Assume 200 ohms of choking impedance on the
outside braid and a 2000+j2000 load. Where will the current go?

Yes, but if the current distribution is such that one gets a reasonable feed-point impedance and relatively low ohmic losses, then the antenna can still be useful. It has been a valid technique for years to bend an antenna around to fit a small lot, and, it does work. The real disagreement, or at least the real question, is whether there is any specific advantage gained with a fractal bending as opposed to arbitrary bending of the same basic physical size. I think that if that question was answered with a statement to what those specific advantages are, most of the discussion could move on. Of course, an answer to the question would mean that most of the discussion would move on. :-)

Roland- the problem of checking a Yagi before taking it to the top of
the tower is the interference with the ground. A common trick that gets
a good first check (not final tweaking) is to point it up. The effect of
the ground is somewhat masked behind the reflector. This looks (to the
antenna) much more like the fields around the final position than just
mounting it on a pole a few feet above the ground, in its normal
orientation.

It's an old trick, and it worked for me.

Hello Ed;

Could you tell me what you found inadequate with my previous answers to this?

Let me summarize to make this easier for you.

1) The advantage of the Mi2 Loop designs is they offer an OPTIMUM FIGURE OF MERIT for performance: that is, the greatest directivity , efficiency, bandwidth, and match for their very small size, WITHOUT THE USE OF ADDITIONAL COMPONENTS.
2) the general question of a fractal advantage is many-fold, I will concentrate

on two: 1) all frequency independent antennas must be self similar and are thus fractal; you cannot construct a freq indep antenna which does not incorporate self similarity; 2) it has been shown that oprtimized antenna designs are fractal. A good place to start on this is OPTIMIZATION OF WIRE ANTENNAS by Landstorfer and Sacher.

Fractal antennas are experiencing an explosive growth in commercial uses, chiefly because they offer small, high performance antennae without the issues of matching, reliability, and manufacturing cost associated with conventional designs.

I am astounded, I must admit, by your description of the Steve Best designs as "arbitrary". Wow! In fact, NONE is arbitrary; all are fractals and meanders; and, indeed, are thus covered by prior art of extant pending patents.

The real issue with the Best antennas, besides the fact that they are neither 'random' nor 'arbitrary', but are in fact 'fractal' or 'meander' is: how accurate are they as models cpmared to real antenna versions? One particular problem is that one ignorant perdson has claimed is that "550 segments! Wow! You don't need that many!" In such a claim and by reducing the current density so that small wires have disparate current samplings from longer ones, that person has substantially increased the imprecision and systemic inaccuracy of the model. Mr. Best, I must stress, is not guilty of this.

The meanders are less accurate than the others; I have made a scaled version of the meanders on 4003 substrate and find them no where near the return loss, directivity, or resonance so predicted. In fact, I think it is important for Best or others to actually make and test these antennas, which is straight forward as scaled etchings.

As I have stated, I applaude Mr. Best in his effort to find better loops, and frankly it is heartening to see that he, for himself, has discovered better fractal loops! However, the need for more methodical approaches is clear, and thus my allusion to a MS I will submit in a few weeks.

As far as the ham MI2 design, I have been unable to produce an HF MI2 loop with a 26 ohm impedance. Neither has anyone else.The drive resistances are always far higher, in excess of 40 ohms (with very little of this ohmic) .

Try it yourself. Bend an MI2 as described on the web page link on

http://www.fractenna.com

and tell us what drive resistance you get. I bet you a cookie you will get a nearly flat SWR across a large bandwidth. Furthermore, the only way to get a 26 ohm resistance is to have the inside corners nearly touching, as suggested by the nuance of the model. In practice this does not occur and is not shown in any pictures of the MI2 or its FQY version.

I remind readers that the issue that has noxiously been applied is the unuathorized distribution and publication of the MI2 file and its clearly derivative copies. This is not a 'science' issue but an intellectual property issue and both Fractal Antenna Systems,Inc. and I are starting the first steps

to legally stop and punish the two major offendors of the respective ifringements of MI2 and other files..

I also remind readers that, for private use, I have ALWAYS provided copies of the MI2 file as requested from members of the fractal antenna reflector. Thus the file is readily available and always has been. This does not, and will not, however, in any way justify or allow for illegal publishing and distribution of said copyright material.

With Best Wishes,

Chip N1IR

Well, recently MFJ bought out Vectronics, so it would be no surprise
if the units are the same or similar. Go to the Vectronics site,
www.vectronics.com and the MFJ site, www.mfjenterprises.com and you
can compare the units directly.

Barry, WA4VZQ wrote:
"Remember I was talking about a short base-loaded whip, like most CB antennas for trunk or roof mount."

Kevin, the original questioner, wrote:
"1) Can you recommend a 10 meter antenna to me?"

Jeff gave the first response:
"On antennas. For under $29.00, use a Francis 108" whip and add a little length to it."

We are all free to be responsive or divert the discussion. We are also free to tease CBers by suggesting their antennas need more length.

My point was that the ordinary stainless 108-inch CB antenna was pretty good at 10 and 11 meters, and that other materials would not make enough improvement to be worth the trouble.

From "The Science of Fractal Images" by Peitgen and Saupe:

"This property of objects whereby magnified subsets look like
(or are identical to) the whole and to each other is known as
self-similarity. It is characteristic of fractals and differentiates
them from the more traditional Euclidean shapes (which, in general,
become ever smoother upon magnification)."

Once again you state that ALL antennas are fractals because they are self similar.

Next you claim that you have all the patent pendings on fractal antennas.

While your recent posts show a return to rationality, your claims unfortunately have failed to make the same turn.

I was wondering if there would be any advantage to using a continuously loaded 1/2 wave antenna (wound on a 9 foot length of fiberglass) over using a straight 1/4 wave whip on 10 meters? Would winding the 1/2 wave on a 9 foot section be too short to provide any benefits of the 1/4 wave? Is shunt fed the best way to feed the 1/2 wave?

Scott.

Source record: 177267

Robert Bukowski wrote:
"Now I am using an antenna consisting of 7 elements, but the signal is weak (44dB)."

A 7-element UKW (ultrashortwave) antenna should have good gain and directivity.

First, make sure that the antenna performs. Gain is important to capture the distant 94.3 station. Directivity which causes the gain is important to reject signals from unwanted directions.

Use the best antenna you can. Put it as high as you can. Signal strength from a distant station is proportional to antenna height. Rotate the antenna for best reception (either most signal or least interference).

Check antenna cable and connections.

Best regards, Richard Harrison, KB5WZI

The "Best Antennas" are NOT fractal antennas!

Fractal antennas represent a class of electromagnetic radiators whose overall structure is comprised of a series of repetitions of a single geometry (the geometry basis), where each repetition is on different (or in some cases, the same) scale. Most fractal geometries are self-similar in that some portion of their geometry has the same shape as the overall geometry, only at a reduced scale.

Here is the definition of fractal antennas per N. Cohen in a paper entitled "Fractal Antennas Part 1 - Introduction and the Fractal Quad", Comm Quart, Summer 1995: ".... Following in that tradition of nonlinearity, the newest branch of geometry is called fractal geometry. Here a complex structure us built up through the repetition of a design or motif (sometimes called a generator) on a series of different scales. Such structures are called self-similar."

Here is the definition of fractal antennas per C. Puente-Baliarda in a paper entitled "On the Behavior of the Sierpinski Multiband Fractal Antenna", IEEE Transaction on Antennas and Propagation, April 1998: "Most fractal objects have self-similar shapes, which means that some of their parts have the same shape as the whole object but at a different scale. ..... In such an interactive procedure, an initial structure called a generator is replicated many times at different scales, positions and directions, to grow the final fractal structure."

In the MI2 loop antenna, the "generator" sits in the center of the structure and it is repeated four additional times in the structure from each corner

of the generator. The antennas that I designed are arbitrary in shape, in that in one quadrant, I rearranged the wire length into an arbitrary shape. I then created the total antenna by mirror imaging the wire shape in the first quadrant into the other three quadrants, thus the antennas are symmetrical. An antenna being symmetrical does not mean that it is a fractal.

At this point, Chip is declaring that my antennas are fractal. I can only assume that this claim is made on the basis that the antennas are symmetrical in shape. If this is true, then Chip is stating that all symmetrical antennas are fractal. This would then mean that "fractal" antennas have been designed and used for well over 50 years and we have now just decided to call them "fractals" rather than symmetrical. This has serious implications for all IP and patent claims. One cannot have it both ways.

Hi Steve,

You do not do justice to the definition of fractal geometry by quoting me incompletely and out of context. For example: how do you thus deal with the fact that random fractals are thus described at length in the same article?

Are clouds fractal? Are mountains fractal? These are examples which you may choose to explore in greater depth.

It would be unfair to you and certainly to others who read your posts, for your absence of knowledge of fractal geometry to be repeated and even used legally.

All my statements are accurate --especially regarding the non-meander designs you have described-- which are covered by pending patents--and havebeen for some time-- by Fractal Antenna Systems,Inc.

They are not random and not arbitrary.

I make no claims whatsoever about the fractality of a shape merely because it is symmetrical. I am well aware of the difference between self similarity and symmetry.

I regret that I am not in a position to further aid you on these issues, as you have systematically ignored my efforts to assist you previously, and there is a large body of published work extant on fractals.

Cordially,

NC

1573. Mast in vertically polarized antenna?

Message-ID: <20001101100046.18299.00000016@ng-fe1.aol.com>
Source record: 177271

Question about some practical experiences and requirements for the metal mast in the vertically polarized antennas.
Let's say we have Quad or Yagi that is vertically polarized and we want to have it on a single mast (vertical). Is using the balun for the feedline enough to decouple it? Should mast also be "broken up" into non resonant lengths or would it appear "invisible" if it is half way up in the antenna?
No Freakin' theories, just the practical or measured experiences please.

Hi Richard,

One imperfect example would be to look closely at a log periodic antenna - say 5 or 6 elements of a much longer construction. As you examine these elements you will note a basic underlying principle of construction.

Then step back so that you see even more elements (let's pretend that's 10 or 12 of them on a much longer construction). As you examine these elements you will note a basic underlying principle of construction.

The basic underlying principles of the two examinations will be the same even though scale and number of elements have changed.

A log periodic thus appears to be scale independent, or self-similar at any scale.

This, however, is NOT the principle mechanism of discussion with the popular conception of fractal antennas (which is largely based on the employment of standard forms). Here when self similarity is trotted out to explain them, it is the similarity between iterations of the form. In this sense, you might imagine a snowflake being built. As the ice crystals accumulate to construct the flake, it changes form, but generally always exhibits one principle shape (hexagonal).

I have a page that illustrates the progression of iterations:
http://www.qsl.net/kb7qhc/antenna/fractal/Triangle%20Sweep/index.htm
and it is said, a picture is worth 100 zipped up bytes.

This is about the simplest form, and you will note that each iteration has two copies of the previous iteration in it. Going through 5 iterations reveals a complex form made up of the original first iteration in many combinations still filling roughly the same footprint.

Hi All,

With as many responses to this page as I've had, come one and all and download your own copies of these files and determine for yourself why the n1ir design is so tepid. Continue the grand tradition of improving on a design that has been anointed as optimal!

Just recently the k2 ground warmer was proclaimed to be unbeatable (we've heard that one too often) by its designer - only to be improved by my own poor attempts to copy it. You may find that you too have that magic touch that turns fractals into shinola!

and remember
DO NOT RESPOND TO TROLLS AND ESPECIALLY FRAUDS

Nathan:

Aside from the "absence of knowledge" dig, thank you for the mostly straightforward and respectful post. I think its much better to deal with people respectfully and on par.

My quoting of your definitions were not meant to be taken out of context as the definition seems to be consistent with those presented by others. The issue then, is how do you define a fractal loop antenna? If a loop antenna is not self-similar why is it a fractal? What is an example of a non-fractal loop?

On the Kraus SLA issue, I would appreciate a technical rebuttal (one that does not begin with "Steve has an absence of knowledge issue ....."). Looking further, I would agree that Kraus's SLA approximation does not provide accurate results for the MI2 loop at the upper end of the area limit. I still think its inappropriate to declare it "incorrect". "Not applicable" might be a more politically correct term to use since anyone could say you were using the SLA out of the intended context. I will probably sent out one more post on the Kraus issue - I will maintain the technical nature of the discussion and would appreciate the same from you.

Steve

It minimizes the influence of a near earth ground. Mounting a Yagi
horizontal on a short mast close to the earth for convenience in tuning
causes the results generally to be quite different when the antenna is
mounted at its service height.

On the other hand, nounting it so that "it points straight up" tends to
minimize near earth effects and allows one to make tuning adjustments
that are only slightly changed when the antenna is elevated.

This is a very old dodge for tuning directive arrays near the earth
without getting near-earth effects.

Hahaha! And you consider than an _advantage_?? :-)

There's another similarly inexpensive program that works in inches,
and also makes it easy to use standard US machine screws for forming
the turns, if you wish. It gives an estimate of Q and self-resonances
as well, as I believe Reg's program does. (The two don't agree
exactly, but either should be close enough for any design work that
amateurs would normally be doing.) The "other" program is available
at http://www.saratogasoftware.com/pages/freesoft.htm

(It's also quite easy to put the old but very useful
L=(n^2*r^2/(9*r+10*l)) formula into a spreadsheet, and even munge it
around to accomodate mm, cm, inch, cubit, or whatever measurements. But
it's really nice to have the Q and self-resonance figures that the other
programs give, too.)

Cheers,
Tom

Note that the definitions for "fractal" you quote are over-constrained.
A fractal has some characteristic which is invariant at several scales,
but that characteristic need not be a particular, unvarying shape. The
scale-invariant characteristic may instead be some statistical measure
of the geometry. For example, a cloud is often given as an example of
a fractal geometry in nature. Clouds are randomly shaped, so there is
no deterministic generator geometry which defines their "fractalness",
they are instead fractal because some statistical measure of the geometry
is invariant at several scales.

It hence isn't the case that your antennas are not fractal antennas
simply because they lack a fixed generator geometry. On the other hand,
it isn't the case that all bent-up shapes are fractals either. For the
shapes to be fractal there needs to be some characteristic which is
invariant at several scales.

>At this point, Chip is declaring that my antennas are fractal. I can only

>ways.

I don't think he is making the claim based on the symmetry of the
antenna (even deterministic fractals are often not symmetrical). The
real problem is that he is declaring the antennas to be fractal while
giving no hint at all about the scale-invariant characteristic on
which the declaration is based. Without a description of the latter
the declaration has no basis.

The Mandelbrot set is self-similiar. The closer you look, the more little Mandelbrot characters you see.

A coastline is self-similiar. Just from the jagged line defining a coastline, it is difficult to say whether it appears that way from 30,000 ft or from 100 ft away.

A von Koch snowflake is somewhat like an antenna. The first stage looks like:

```
/\
/ \
/ \
/ \
-------- --------
```

There are four lines. Take each of those four lines and turn it into a smaller design like the above. You have 16 small lines. Take each of those 16 lines and turn each line into a smaller design like the above. You have 64 small lines. Keep it up to your heart's content. The smallest set of four lines will have the above form factor. The area occupied by the lines remains approximately the same while the total length of the lines gets larger and larger. Feed it in the middle and keep bending until it is resonant on the desired frequency.

Al, yes your RG-6 quad is buriable. There is a version designed for
underground. It is flooded cable. There is a sticky flooding compound
between the jacket and the braid. This will seal small nicks in the
jacket and help prevent moisture contamination.The flooded would be
preferable, but since it is a short run, you will probably be fine with
whatever you have.

How quick we forget...

I invented the internet
I was the model for love story
My mother pays more for her medicine than the same medicine for her dog
I voted for campaign reform (Before I was even in elected office)

ad nasium

Now would you care to quote the context of the Bush remark or shall I?

He may have said it as part of a complete thought, but taken out of context
to put a liberal spin on it is typical.

To use your tactic, I could quote your post as:

"RanHefner" <ranhefner@my-deja.com> wrote in message
news:8tpomcboj1@nnrp1.deja.com...

"Not a crackhead anymore!"

HOW TO TURN SIX DOLLARS INTO SIX THOUSAND DOLLARS: : READING THIS =
COULD CHANGE YOUR LIFE! IT DOES WORK! : I found this on a bulletin board =
and decided to try it. A little : while back, I was browsing through =
newsgroups, just like you are now, : and came across an article similar =
to this that said you could make : thousands of dollars within weeks =
with only an initial investment of : $6.00! So I thought, "Yeah right, =
this must be a scam", but : like most of us, I was curious, so I kept =
reading. Anyway, it said : that you send $1.00 to each of the 6 names =
and address stated in the : article. You then place your own name and =
address in the bottom of : the list at #6, and post the article in at =
least 200 newsgroups. : (There are thousands) No catch, that was it. So =
after thinking it : over, and talking to a few people first, I thought =
about trying it. I : figured: "what have I got to lose except 6 stamps =
and $6.00, : right?" Then I invested the measly $6.00. Well GUESS =
WHAT!?... : within 7 days, I started getting money in the mail! I was =
shocked! I : figured it would end soon, but the money just kept coming =
in. In my : first week, I made about $25.00. By the end of the second =
week I had : made a total of over $1,000.00! In the third week I had =
over : $10,000.00 and it's still growing. This is now my fourth week and =
I : have made a total of just over $42,000.00 and it's still coming in : =
rapidly. It's certainly worth $6.00, and 6 stamps, I have spent more : =
than that on the lottery!! Let me tell you how this works and most : =
importantly, WHY it works... Also, make sure you print a copy of this : =
article NOW, so you can get the information off of it as you need it. : =
I promise you that if you follow the directions exactly, that you : will =
start making more money than you thought possible by doing : something =
so easy! : Suggestion: Read this entire message carefully! (print it out =
or : download it.) Follow the simple directions and watch the money come =
: in! : It's easy. It's legal. And, your investment is only $6.00 (Plus =
: postage) : IMPORTANT: This is not a rip-off; it is not indecent; it is =
not : illegal; and it is 99% no risk - it really works! : If all of the =
following instructions are adhered to, you will receive : extraordinary =
dividends. : PLEASE NOTE: : Please follow these directions EXACTLY, and =
$50,000 or more can be : yours in 20 to 60 days. This program remains =
successful because of : the honesty and integrity of the participants. =
```

Please continue its : success by carefully adhering to the instructions. =
: You will now become part of the Mail Order business. In this business =
: your product is not solid and tangible, it's a service. You are in : =
the business of developing Mailing Lists. Many large corporations are : =
happy to pay big bucks for quality lists. However, the money made : from =
the mailing lists is secondary to the income which is made from : people =
like you and me asking to be included in that list. : Here are the 4 =
easy steps to success: : STEP 1: Get 6 separate pieces of paper and =
write the following on : each piece of paper "PLEASE PUT ME ON YOUR =
MAILING LIST." Now : get 6 US $1.00 bills and place ONE inside EACH of =
the 6 pieces of : paper so the bill will not be seen through the =
envelope (to prevent : thievery). Next, place one paper in each of the 6 =
envelopes and seal : them. You should now have 6 sealed envelopes, each =
with a piece of : paper stating the above phrase, your name and address, =
and a $1.00 : bill. What you are doing is creating a service. THIS IS =
ABSOLUTELY : LEGAL! You are requesting a legitimate service and you are =
paying for : it! Like most of us I was a little skeptical and a little =
worried : about the legal aspects of it all. So I checked it out with =
the U.S. : Post Office (1-800-725-2161) and they confirmed that it is =
indeed : legal. Mail the 6 envelopes to the following addresses: : #1)=20

E. Benford : 6656 Mableton Pwky APT.#D4 : Mableton, GA.. 30126 : =
#2) Kim Williams : 3334 Kingsland Avenue : Bronx, NY 10469 : #3) Yury =
Konev : 823 Pavonia Avenue : Jersey City, NJ 07306 : #4 A. Campbell : =
P.O. Box 432 : Nellysford, VA.. 22958 : #5B. Page. PO Box 5024 Kendall =
Park NJ 08824 #6 Ewald Kerkhoff site 41 comp. 30 Penticton, B.C. V2A =
7K8 Canada : STEP 2: Now take the #1 name off the list that you see =
above, move : the other names up (6 becomes 5, 5 becomes 4, etc...) and =
add YOUR : Name as number 6 on the list. : STEP 3: Change anything you =
need to, but try to keep this article as : close to original as =
possible. Now, post your amended article to at : least 200 newsgroups. =
(I think there are close to 24,000 groups) All : you need is 200, but =
remember, the more you post, the more money you : make! You won't get =
very much unless you post like crazy. :) : This is perfectly legal! If =
you have any doubts, refer to Title 18 : Sec. 1302 & 1341 of the Postal =
lottery laws. : Keep a copy of these steps for yourself and, whenever =
you need money, : you can use it again, and again. : PLEASE REMEMBER =
that this program remains successful because of the : honesty and =
integrity of the participants and by their carefully : adhering to the =
directions. Look at it this way. If you are of : integrity, the program =
will continue and the money that so many : others have received will =
come your way. : NOTE: You may want to retain every name and address =
sent to you, : either on a computer or hard copy and keep the notes =
people send you. : This VERIFIES that you are truly providing a service. =
(Also, it might : be a good idea to wrap the $1 bill in dark paper to =
reduce the risk : of mail theft.) : So, as each post is downloaded and =
the directions carefully followed, : six members will be reimbursed for =
their participation as a List : Developer with one dollar each. Your =
name will move up the list : geometrically so that when your name =
reaches the #1 position you will : be receiving thousands of dollars in =

CASH!!! What an opportunity for : only $6.00 ($1.00 for each of the =
first six people listed above) Send : it now, add your own name to the =
list and you're in business! : ---DIRECTIONS ----- FOR HOW TO POST TO =
NEWSGROUPS---------- : Step 1) You do not need to re-type this entire =
letter to do your own : posting. Simply put your cursor at the beginning =
of this letter and : drag your cursor to the bottom of this document, =
and select 'copy' : from the edit menu. This will copy the entire letter =
into the : computer's memory. : Step 2) Open a blank 'notepad' file and =
place your cursor at the top : of the blank page. From the 'edit' menu =
select 'paste'. This will : paste a copy of the letter into notepad so =
that you can add your name : to the list. Step 3) Save your new notepad =
file as a .txt file. If : you want to do your postings in different =
settings, you'll always : have this file to go back to. : Step 4) Use =
Netscape or Internet explorer and try searching for : various newsgroups =
(on-line forums, message boards, chat sites, : discussions.) : Step 5) =
Visit these message boards and post this article as a new : message by =
highlighting the text of this letter and selecting paste : from the edit =
menu. Fill in the Subject, this will be the header that : everyone sees =
as they scroll through the list of postings in a : particular group, =
click the post message button. You're done with : your first one! =
Congratulations...THAT'S IT! All you have to do is : jump to different =
newsgroups and post away, after you get the hang of : it, it will take =
about 30 seconds for each newsgroup! **REMEMBER, THE : MORE NEWSGROUPS =
YOU POST IN, THE MORE MONEY YOU WILL MAKE! BUT : YOU HAVE TO POST A =
MINIMUM OF 200** That's it! You will begin receiving : money from around =
the world within days! You may eventually want to : rent a P.O.Box due =
to the large amount of mail you will receive. If : you wish to stay =
anonymous, you can invent a name to use, as long as : the postman will =
deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE : CORRECT.** : Now, : =
each of the 5 persons who just sent me $1.00 make the MINIMUM 200 : =
postings, each with my name at #5 and only 5 persons respond to each : =
of the original 5, that is another $25.00 for me, now those 25 each : =
make 200 MINIMUM posts with my name at #4 and only 5 replies each, I : =
will bring in an additional $125.00! Now, those 125 persons turn : =
around and post the MINIMUM 200 with my name at #3 and only receive 5 : =
replies each, I will make an additional $625.00! OK, now here is the : =
fun part, each of those 625 persons post a MINIMUM 200 letters with : my =
name at #2 and they each only receive 5 replies, that just made me : =
$3,125.00!!! Those 3,125 persons will all deliver this message to 200 : =
newsgroups with my name at #1 and if still 5 persons per 200 : =
newsgroups react I will receive $15,625,00! With an original : =
investment of only $6.00! AMAZING! When your name is no longer on the : =
list, you just take the latest posting in the newsgroups, and send : out =
another $6.00 to names on the list, putting your name at number 6 : =
again. And start posting again. The thing to remember is: do you : =
realize that thousands of people all over the world are joining the : =
internet and reading these articles everyday?, JUST LIKE YOU are : now!! =
So, can you afford $6.00 and see if it really works?? I think : so... =
People have said, "what if the plan is played out and no : one sends you =
the money? So what! What are the chances of that : happening when there =

are tons of new honest users and new honest : people who are joining the =
internet and newsgroups everyday and are : willing to give it a try? =
Estimates are at 20,000 to 50,000 new : users, every day, with thousands =
of those joining the actual : internet. Remember, play FAIRLY and =
HONESTLY and this will really : work.=20

Andrew Young wropte:
"WOW how much free space do you have?"

Andrew`s 50 ft by 15 ft antenna space might work almost like free space were he to scale down the rhombic by a factor of 100 except for the antenna support poles which remain at 60 feet. The rhombic should then deliver very nearly the predicted 11 dbd gain at 3 Gigahertz.

Best regards, Richard Harrison, KB5WZI

>

I gave you the context before, but I will do it again in the hopes that
you will be more receptive this time.

A web site, http://www.gwbush.com , was giving GW Bush a pretty hard
time on their web site. Bush was confronted about it by reporters. GW
BUSH made the now infamous statement listed below. He was saying that
the web site should not be able to use his name to bash him on the
internet. GW wanted to limit his freedom to publish a parity site
about GW.

Now, post the quote from Al Gore that said as you say "he invented the
internet."

1609. Re: Rhombic antenna for 10m

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-01 22:06:25 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A0093E1.60E996B@eznec.com>
Source record: 177308

It's a common misconception that an antenna mounted high above ground will act like an antenna in free space. This is true only if there's no path from the antenna to the observation point (where the antenna pattern is observed) via reflection from the ground. This might be the case, for example, for a highly directive antenna mounted on a hilltop when observed from another nearby hilltop located in the main beam. But overall, the pattern of a very high antenna has many, many lobes and looks nothing like a free space pattern. Ground reflection doesn't cease as you get higher -- it just occurs farther and farther from the antenna for a given elevation angle. In practice, ground irregularities, multipath, and so forth will fill in and/or move the pattern nulls. And the flat-ground approximation used by the modeling programs will become increasingly inaccurate as the height is increased to the point where the Earth's curvature is significant. But even with these considerations, the pattern of an antenna mounted high above the ground is very different from that of a free space antenna.

The more interesting question is why is it important for you to be
secretive about it.

You wanted to know what you could add to clarify, and I suggested that
the names of the journals might do it. Each type journal has its own
type of review process. The names of the journals would allow us to
know the type of review your MS will undergo.

>
> Scott.

I'm just guessing, but I would think would depend on how good the radial or ground system is underneath the radiator. If the radial system was good, I don't think it would make much difference. If the radial system was poor or non existent I would think the short 1/2 wl ant "could" be better. It is pretty much complete in itself, and wouldn't "require" radials to operate. An example of this is the short glass antennas, and some of the 1/2 wl HT antennas. But, I don't think the gain of the short 1/2 wave would equal the full size halfwave.
Being it's about 1/4 wl in actual length , I'd think the gain about the same as the 1/4 wave, except a little different current distribution. MK

Of course, if ground is around to produce a reflection it will affect
propagation of a wave.
It won`t have much effect on gain and directivity of a rhombic looking
like a reshaped coathanger atop a 60-ft wooden pole operating at 3 GHz.
This antenna will act as an antenna in free space. The receiver may very
well get a direct signal and a reflected signal from the ground. Dry
ground is usually not too good as a 3 GHz reflector, but the reflection
point will be far from the antenna and have more to do with performance
of a point to point path than the attributes of the antenna.

> improvement to be worth the trouble.

Since Richard wants to be offended, so be it. He obviously did not read my posts in detail. At no point did I fault a full quarter wave whip. My first post was to agree with Bill Nelson who pointed out that KG4FET's statement that a Wilson 1000 magnetic-mount antenna (I have never seen a magnetic mount 108 inch whip) had a 2:1 VSWR bandwidth of 3 MHz is just not possible without this antenna being quite lossy.

My example showed how a shortened antenna could perform almost as well as a full sized one, but at the expense of an extremely small bandwidth.

In the case of the Wilson 1000 antenna KG4FET suggested, the length is 54 inches of precipitation hardening 17-4 stainless. At DC this has approximately 52 times the resistivity of copper. At RF the ratio will be even higher. With only about 6.4 ohms feed impedance, an extra ohm or two of resistance will do a lot to widen the bandwidth - at the expense of efficiency.

A full sized quarter-wave whip will have about six times the feed impedance of the Wilson KG4FET suggested. An extra ohm or two or resistance due to stainless here is a far small percentage and the added loss will be minimal.

Dwight, first of all it's not a group but a society. Something that's equivalent to your ARRL, though a lot smaller but it's an organization with the same purpose as ARRL.

Second, as many have pointed out, why not? There is quite a large group here in Toronto with their roots in Poland, may it be first or second generation Canadians. They would simply like to celebrate the 75th anniversary not only amongst themselves but also with their polish ham friends in Poland and those scattered around the world. Many of them were active members of PZK (Polish Ham Radio Society) and being 4000 miles away from Poland, for one reason or another, are not able to participate in PZK's activities in full capacity.

Sixty feet is about 20 lambda at 3GHz. Suggest you model an antenna 20 lambda high and report back.

No way is it anything like free space.

Free space antenna gains are used in point-to-point path calculations
for terrestrial radio circuits. Real world measurements match
calculations to the decibel during normal propagation.

So, the antennas must be operating as if they were in free space.

Reflection at the path grazing point could affect signal levels. To
minimize this effect, the path is often engineered for 0.6 Fresnel zone
clearance, which would be neutral to path loss. The ringer is, of
course, that a certain atmospheric refraction index is needed to produce
the exact clearance, But the usual practices work very well anyway.

Best regards, Richard Harrison, KB5WZI

For sure, the feedpoint impedance, current distribution, and efficiency of an antenna this high will be virtually the same as for the same antenna in free space. The gain, directivity, and pattern shape definitely will not, as I pointed out in my earlier posting.

What properties do you consider to be "attributes of the antenna" and which aren't? Are these attributes independent of the antenna's environment?

The electrical "earth" should be connected to an outside groundrod via a
ground wire from the electrical panel.

Your electrical "ground" is a safety ground, it is not intended for RF
"grounding" or heavy-duty lightning protection. Simply put,
your electrical wiring is much too long to provide an effective antenna
ground, it simply has too much inductance to "ground" RF energy.

Your ham cables should be properly grounded to an outside ground
rod using suitable protectors that offer tranverse and longitudinal
protection.

All ground rods should be electrically joined together.

Most of this applies to US standards, NZ electrical codes may be
entirely different. I suggest you visit the PolyPhaser website and
read their material regarding proper grounding techiques.

Wes, N7WS wrote:
"Sixty feet is about 20 lambda at 3 GHz."

Let`s make the math easy.
150 MHz is 2M.
300 MHz is 1M.
3 GHz is 10 cm.
10 cm is about 4 in.
2.54 cm = 1 in.
60 ft is 720 in.
720 in / 4 in = 180 wavelengths.

Correction: Sixty feet is about 180 lambda at 3 GHZ.

A signal loses 22db in its first wavelength of travel and an additional 6 db every time the distance traveled doubles after the initial loss of the first wavelength`s travel. Any signal reflected from a surface 180 wavelengths away will be insignificant in its interaction with the radiating element. Mutual impedance is insignificant.

The antenna will behave as if in free space.

Best regards, Richard Harrison, KB5WZI

"For sure, the feedpoint impedance, current distribution, and efficiency of an antenna this high will be virtually the same as for the same antenna in free space. The gain, directivity, and pattern shape definitely will not,"

The attributes of an antenna are the above listed characteristics. The gain, directivity, and pattern shape are the same as in free space.

Changes in signal levels caused by distant reflections which produce multipath problems are path characteristics, not antenna characteristics.

Best regards, Richard Harrison, KB5WZI

I have noticed, Chip, and with great relief! All one need do is poll the back archives to discover who the number-one poster boy normally is on here (the deja-digits speak for themselves). I'd bet, if you keep up the good work for a couple more weeks, most of your non-technical cat-callers will simply go away. Then you can just deal with....well...the technical ones!

I certainly understand the desire to maintain roots with the "motherland," but this just seems a strange way to do it - a "special event" to "celebrate" the anniversary of an radio organization on Poland (an organization that no longer has anything specific to do with that person in Canada). It just makes me wonder if the actual goal is to maintain roots with the "motherland," or to maintain roots with this organization.

I base that wonder on the fact that I've spent many years overseas during the last twenty years and never once did I even consider the notion of a special event to celebrate the anniversary of some organization here in the US.

Of course, it doesn't really matter what I think - you're free to do what you want. Its just that your announcement seemed odd to me, so I decided to ask rather than just walk away with a wrong impression of your intent.

It would seem to mean that EVERY antenna where one half is the mirror
image of the other is fractal and Dipschit has a patent on all of them!
I guess the rest of us are reduced to long wires.

I beg your pardon! I was watching him on TV when he said it. His exact
words were "......I took the initiative and invented the Internet."

It HAPPENED. I saw it and I'm certain many others did as well

It is quite typical of him -and his minions- to now deny that he said
it.

Here's something else he did. My brother watched this on TV-

Gore walked in to Monticello where Clinton and his group awaited.
Observing the busts of all the Founding Fathers on display there, he
commented "And who are all these fine people?" The dingaling didn't
recognize Washington, Jefferson, and the rest! Clinton's jaw dropped
about 8 inches, he clearly was dumfounded by that display of ignorance.

Well, someone is telling you wrong, Gerry. A properly designed grounding system should not cause ground loops at all. The wiring in your house is simply not designed to provide sufficient RF ground for a radio transmitter. You need a dedicated ground rod, or rods, to do this job right.

Furthermore, you need the additional protection from lightning if you install additional equipment than is normally installed in a home (antennas, etc). Again, the house wiring was not designed with this additional equipment in mind.

Install addition grounding for your system (antennas and radio). Use the proper ground rods, installed close to the various parts of your equipment. And use proper ground wire, but keep this as short as possible (it loses effectiveness as an RF ground as it gets longer).

If you find that you have created a ground loop, it can usually be solved by simply moving the ground rods to a slightly different location. If that does not solve it, locate a good book on antenna installations for more things to try.

Of course, all this is accurate here in the northern hemisphere - things might be opposite from this down under. ;-)

"Since Richard wants to be offended, so be it."

If I`m the Richard you mean, I`m not offended. If I`m not, I`m still not offended. You were talking about one antenna, and I was talking about another. I haven`t disputed anything you have posted in this thread.

My CRC Handbook doesn`t seem to give RF resistivities for stainless steel, and neither does my RSGB Handbook. I used to work with these in making dissipation lines for rhombics, but that was almost 50 years ago, and I forget.

RSGB does give aerial efficiencies for 1/8-in diameter wires of copper, aluminium, zinc, and brass, which are: 99.75%, 99.7%, 99.5%, and 99.4%. Not a whole lot of difference.

A saving grace seems to be deeper penetration as the material becomes more resistive, which evens out the differences between the various non-ferrous metals.

Best regards, Richard Harrison, KB5WZI

O really?? I guess the wire is similiar unto itself, ok, but certainly not unto its 'other half', the counterpoise.

I usually use a 60 ft long wire fed with an Alinco EDX2 autotuner and 40 ft of magnet wire laid or coiled on the ground underneath my motorhome when I go camping. Works quite well, but if that's an example of a Fractal antenna then this entire "scientific" subject has gone through rational, past sublime and into sheer and total nonsense.

Thanks for the clarification. Sure, if you define the antenna gain and pattern to be the free space gain and pattern, then certainly they don't change when the antenna is put into a different environment, including being buried underground, let alone being elevated.

I'm sure this is a useful concept when dealing with highly directional point-to-point communication antennas where any signal reaching one from the other from a ground reflection is much smaller than the direct signal. This is seldom the case for most amateur applications, so gain, pattern shape, and directivity generally include the effect of the environment in that context. It's good to be reminded that other conventions are used than the ones we're used to.

Sounds typical of modern electrical systems most everywhere.

> Now I have always believed that a good earth is essential for the
> antenna/earth system

Why? If you use balanced antenna systems with common mode decoupling
there is no reason for needing separate ground systems for your radio
gear. The safety ground in your house wiring takes care of that aspect.
The RF appearing at your antenna doesn't come back to your shack. Why do
you need a RF ground? I don't use one and haven't for many years.

but I have now been told that a separate earth in the
> shack as separate from the electrical household wiring earth will create all
> sorts of problems with earth loops (whatever they are) and that you can
> even get a belt from your rig to the shack earth.

My experience is that most "RF ground" systems cause more such trouble
then they ever begin to solve. Just make sure that your house wiring is
done correctly and that it does indeed provide the necessary safety
ground. If your area experiences thunderstorms and lightning you will
need to deal with that as a separate issue. I unhook all my RF, remote
antenna switch and rotator cables and get them away from the house when
not in use. I also unplug all gear from the AC mains when not in use.

Yeah, I was wondering if a shortened 1/2 wave would produce the more
desirable lobe shape a 1/2 wave has over the 1/4 wave. But I suspect
mounting it so close to the ground might negate that advantage as well.

Scott,
I'm not sure if the effort needed to tune and match a 'shortened',
1/2 wave antenna would be worth the effort, compared to the 1/4 wave
antenna. There is a difference in the two radiation patterns, but
with all the other variables in mobile operations, who knows if it's
going to be worth it? Depending on the type of mobiling you do, as in
'off roading', the fibreglass whip is the draw-back. They tend to
break on the tree limbs...
'Doc

I have created a new antenna that is based on a circle, I have written patent pending all over it and copyrighted with a multitude of (C)'s.

This brings me to the meat of my concerns, I notice that many of you on the newsgroup are using my copyrights by using the letter O in your posts. This must cease, desist, stop, etc etc right now. I will be sending all violators a letter from my attorney for violation of my copyright! You have been warned DO NOT USE THE LETTER O I hold all the patent pendings and copyrights on it and woe be unto anyone who dares to violate my protections. YOU HAVE BEEN WARNED!

There is no need to reply to this post as I am already smarter than anyone on the newsgroup and plan to address totally different issues from thos you may bring up. I will be publishing my data in a pier reviewed magazine, or at least a wharf reviewed one.

Dick Carroll wrote:
"Why? If you use balanced systems with common mode decoupling there is no need for separate ground systems for your radio gear...."

Gerry, hang on to that belief. You don`t need an RF ground with a balanced antenna system. You still need a safety ground to avoid electrical shock, and a lightning ground, if you have ever heard of a lightning stroke where you live. I lived for awhile in Tierra del Fuego. Lightning had never been seen there, but you are farther north.

The reason for a separate ground return to your common earth system is so your radio stuff doesn`t have to share the path to earth with other apparatus. That other apparatus or the wires connected to it could be the source of a huge abrupt current which could cause a proportionately huge voltage drop across the ground return impedance shared with your radio stuff. That could raise the voltage on your radio to a dangerous level. Your radio stuff deserves its own separate ground return wire. It also works the other way. Your radio could be the source of a large surge which you would not want to endanger other apparatus or even the people near it.

You might envision a similar situation with the "phase or hot wire", so it is best to feed your radio stuff with separate wires and a separate breaker or fuse.

You can perhaps use the electrical ground for your electrical service for your RF ground in the unlikely case it is close enough and extensive enough. In any case it must be well connected with all your other earths or grounds.

Think about the common impedance possibilities. They cause most of the surge problems.

Best regards, Richard Harrison, KB5WZI

DC resistivities are difficult enough to predict for the different grades
of stainless!

In the case of the commercial magnet-mount whip, 17-4PH stainless was used.
This is a semi-martensitic material. It get tougher by both work-hardening
and by heating. [The PH stands for precipitation hardening where different
alloy phases precipitate out.] The result is that its resistivity and
permeability are strongly determined by the material's past
mechanical history.

Digging into this taught me something new - even the austenitic stainless
steels like 304, 308 and 316 can, after machining, develop noticeable
magnetic permeability due to strain induced martensitic transformation.
Austenite has a face-centered cubic crystalline structure which is not
ferromagnetic. Plastic deformation during machining causes a phase change
to the martensite body-centered tetragonal crystalline structure which is
ferromagnetic. I am more familiar with the corrosion properties of the
stainless steels than I am of their electrical properties. I was aware
that machining could reduce the corrosion resistance of the austenitic
stainless grades. This explains why since the martensitic grades have less
corrosion resistance.

{Comparing the RF resistivity of copper, aluminum, zinc, and brass}
> A saving grace seems to be deeper penetration as the material becomes
> more resistive, which evens out the differences between the various
> non-ferrous metals.

Unfortunately, if the conductor is ferromagnetic, the skin depth decreases
making the RF resistance increase even more with frequency than it does
with non-magnetic conductors.

By the way, Laport in "Radio Antenna Engineering" discusses the use of
high-loss transmission lines as rhombic terminations. Both regular steel
and stainless were used.
This might be a good use for that roll of constantan thermocouple wire I
have in the garage.

Thanks for stirring up my interest in this.

Lots of replies, and they are all correct... under specific
circumstances.

There are several considerations in adding an RF earth:

* Mains safety
* Lightning protection
* RF grounding
* RFI

In a normal household situation with a lot of pre-existing wiring, it's
very difficult to achieve all of these at the same time. (Starting from
scratch, it can be done using a common earthed entry panel for all
services - and I do mean *all* - but we seldom have that opportunity.)

Also there are mains wiring regulations that will apply to your
installation. Regulations vary from country to country, partly due to
custom but also due to the frequency/severity of lightning. Some things
we can do in the UK are justifiable in this country, but are illegal
under the US National Electrical Code. The reverse certainly applies
too. Don't know how you're fixed in NZ.

Coming to one specific point:

It's certainly true that with an upstairs shack and an antenna that is
supposed to be balanced, you don't need an RF earth. Sometimes an RF
earth or the mains earth can actually "invite" common-mode RF currents
where they wouldn't otherwise exist. Certainly the connection to mains
earth will allow RF currents to flow into the mains wiring, with a
significant risk of RFI. In such cases, an effective solution is to wind
the shack mains cable - all three cores of it together - into an RF
choke. This discourages RF currents from flowing into the mains, and has
no mains safety problems because earth continuity is maintained.

About 10 turns of 3-core mains cable on a stack of about 6 x 2in ferrite rings (or big hunk of ferrite like a scrap TV deflection yoke - which is free) will make an effective RF choke for the HF bands.

BUT if you then plan to add an RF earth at the "shack" side of the RF choke, you may run into problems with local regulations about how different earths can be joined together. Advice from outside your own country may not be valid - it may even be illegal for you - so you MUST check locally.

If you can do it, it's still a very good principle to use a separate RF earth if RF earthing is needed, and choke off the mains conductors to keep any stray RF on the "radio" side where it belongs.

Hello Brian, this is a way to go as well. Problem is, that the
anniversary falls sometime in December so they don't have much time to
get the ball rolling. Unfortunately, I am not the organizer of these
festivities but have been asked to see if I can drum up support on the
Internet, so I cannot really be blamed for doing this a little too late.
But as they say, better late than never.. :)

thanks Brian.

>

You have cited what is, in my opinion, the best book ever written to teach the underlying fundamentals of antennas, transmission lines, RF networks, and propagation without getting into the level of math with which they teach those subjects in BSEE programs. In fact, most EEs would understand those subjects much better if they studied the book.

The book went out of print in the 1960s and has become increasingly hard to find over the past 25 years. I have good news for anyone who is interested in getting a copy, though. A reprint edition has just come out. It is available from:

http://www.noblepub.com

Pardon me for straying off topic. I wanted to share the news. I arranged for the reprint edition and traded the publisher my clean copy for that purpose, but have no financial interest in the project.

Oh yes, I have always been kinda fascinated with Griffith's treatment of toroid feeding of an antenna.

Been following that 'scratch' or 'tick' sound around using the 1-MHz up/down function on my 0.03-30MHz receiver. Seems to be higher in frequency during daytime, and lower at night.

Above it seems 'dead'; below it, signals. It seems to parallel the diurnal pattern of SWBC station audibility here in Cincinnati.

It seems always to be 'there'.

Is it an OHR? Sounder? Is it a reliable indicator (of what)?

It is not about you, Chip; it is about a subject that, due both the number of posts and the content, appear out-of-proportion to other antenna posts. That is generally how and why new newsgroups get started. Perhaps we could take this thread to a formal RFD and see if we can find someone who appears to be neutral to hold the vote, if the concensus appears toward forming a new NG. I just mused that if the original poster is correct, with over 80% of the posts related in some way to fractal antennas, then a new NG would be the normal recourse. Few have called the formation of a new NG "appalling."

I am no more able to control the actions of those posting opinions you do not like than I am able to control your actions, Chip. Are you really suggesting rraa become a moderated group and that I be appointed as moderator? :-)

When things get out of hand, as they are here in some threads, generally all who participate can assume a fair share of the blame. That includes me and you. We cannot control others, but we can control ourselves and, when we post, we should all ask ourselves what the overall effect of that post will be and whether it is really the effect we want to achieve. If we know what will happen when we post something, and do it anyway, we ARE responsible for the outcome.

Well, let's see exactly what what libel and abuse I am self-responsible for in a small tim window, as of late:

0) Writing my employer stating without any question that I am mentally ill? Nope.
1)Being called a homosexual dying of AIDS? Nope.
2) Being called a garbage man in Miami? Nope.
3) Being called a fraud; unwilling to answer questions?; Nope
4) Being called a pirate who breaks the law and downloads illegal files? Nope;
5)Being called an unemployed fiddle player--bastardized to "horse's-ass"?; Nope;
6)Being called someone who claims all antennas are fractal? Nope.
7) Being called 'fired from my academic position ' for poor treatment of students? Nope.
8) Being called "dipchit" and worse? Nope.
9) Being labelled a troll; troll; troll? Nope.

This is a very small subset of it all. Basically I have posted very, very little--and certainly encouraged and provoked no one.

Accept the fact that this NG--and ham radio--has made herculean efforts to embarrass itself. I am sure that one may fall back on: 'its only a small minority', but the fact is that there is a very serious breach of human decency here, and non one sems to want to stop it.

That I am a focus is certainly not my desire and certainly NOT my fault. The only way to stop it is for word to leak out that legal proceedings are happening. NOTHING else will stop it. If you don't believe this, then just list the posters under the relevant topics and you will see that they just feed on themselves, spreading misinformation, abuse, and libel without a word out of me.

Witness the demise of the reputation of ham radio.

Nathan Cohen, Ph.D.

"---Laport in "Radio Antenna Engineering" discusses the use of high-loss transmission lines as rhombic terminations."

Ed Laport mentions Alloy 430 (18% chromimum) which has a resistivity forty times that for annealed copper and is magnetic.

There are many varieties od stainless steel, some magnetic, and some non-magnetic. The alloy we used in dissipation lines wasn`t springy like that used in whip antennas. It was probably lossier than the whip variety, too.

Thanks for reminding me of Laport`s treatment, which is really a treat.

Hi Ed:

I have been informed that symmetry is not the issue in declaring the other loops "fractals".

It would be very helpful if Chip simply answered a few questions:

1) How do you define a fractal loop antenna?

2) If a loop antenna is not self-similar why is it a fractal?

3) What is an example of a non-fractal loop?

Quite frankly, I would be interested in the answers and discussion.

Especially if the length to ground is an odd 1/2 multiple? Straight out of the handbook ;)

>

It was my thought that even if you didn't have common mode currents flowing, isn't it still possible that the coax (outter braid) is picking up a fairly strong signal being radiated from the antenna? Couldn't this flow back down the coax (outter braid again) and be re-radiated, in the shack? Would a functioning RF ground stop this? Or doesn't it even happen?

Scott.

Cecil, first you say the current on the centre conductor (of a mismatched terminated cable) is matched by a differential curent on the inside of the braid. Agreed, these two currents are always equal and opposite to each whether the cable is correctly terminated or not.

Then you say it isn't because some flows on the outside merely because it is mismatched with a high impedance.

Which way do you want it ? You cant have it both ways.

Assuming the generator is at the other end of the coax, take the extreme case and suppose the termination is an open circuit. Is there any current on the ouside of the coax ?

Reg.

Richard can rest easy. Let's take a look at the record.

On September 28 I received an email message from Nathan Cohen, Ph.D., an officer of and representing Fractal Antenna Systems, Inc., claiming that I was infringing a copyright held by that company and requesting that I remove a file from my web site. (He posted a copy of that message on this newsgroup on October 22.) I responded that I don't believe I'm infringing anyone's copyright, and refused to remove the file.

On September 29, Fractal Antenna Systems, Inc., represented by its Chief Technology Officer (Nathan Cohen, Ph.D.), posted a notice on this newsgroup in which it refers to the posting of the file as "copyright infringement", and says that downloading the file will be to "break copyright law".

On October 21, "Chip, N1IR", posting from the Fractenna email address but not identifying the posting as being on behalf of Fractal Antenna Systems, Inc., said that the copyright of the file which Fractal Antenna Systems, Inc. had claimed was infringed was transferred to him.

Beginning on that date and continuing at least through October 25, in public postings on at least six newsgroups, one reflector, and one mailing list, "Nathan Cohen, Ph.D." and "Chip N1IR", posting from fractenna@aol.com (presumably a Fractal Antenna Systems, Inc. account) but not identifying the postings as being on behalf of FAS, called me a "pirate" or accused me of "piracy" on more than ten different occasions. He also stated many times without qualification that I am guilty of

"stealing" his property and am violating a copyright he claims to own.

These statements were made without one shred of credible evidence as to their truth. During this time, except for a short response to my response to the original email message of September 28, I was not privately contacted by Fractal Antenna Systems, Inc., Nathan Cohen, or an attorney representing either.

If true, these statements could -- and should be -- proven in court. And both Fractal Antenna Systems, Inc. (FAS) and Nathan Cohen, Ph.D. stated clearly that they intended to do so. FAS said, on September 29 that I am "being formally sent a letter requesting that [I] cease and desist the further distribution of this copyright material and will have until December 15, 2000 to comply." On September 30 and again on October 1, FAS said in postings that "Mr. Lewallen is being formally sent a letter requesting that he cease and desist the further distribution of this copyright material and will have until December 15, 2000 to comply. Failure to do so will lead to suit against Roy Lewallen d/b/a Lewallen consulting/EZNEC."

On October 21, Nathan Cohen posted a message stating that "Mr. Lewallen HAS BEEN SENT [caps mine] a certified letter formally asking him to cease and desist. If he does not remove the material he will be sued d/b/a EZNEC." This message was posted on at least six newsgroups, one reflector, and one mailing list. On another posting of that date, he said that "Shortly, Mr. Lewallen will receive 'ominous mail from massachusetts' as he calls it-- which will formally tell him to cease and desist from copyright violation."

On October 24, "This is NOT some game. Before the first of the month, Roy Lewallen will received [sic] a registered letter demanding that he remove the MI2 file. If he does not , then legal action WILL--repeat WILL be taken. This will be a costly and losing battle for him. . ."

The first of the month has come and gone, and eleven days have passed since the date when Cohen claimed a letter had been sent.

I have not received the letter which Fractal Antenna Systems, Inc. said would be sent, or the registered and certified letters Nathan Cohen has said would be sent.

Nathan Cohen, Ph.D., aka Chip, N1IR, has publicly and frequently, and without qualification, accused me of stealing and piracy, without any evidence whatsoever to establish the truth of these charges. An officer of Fractal Antenna Systems, Inc., speaking on behalf of that company, has also publicly accused me of copyright infringement without evidence. I, and much less all the people to whom these charges were publicly presented, haven't seen even so much as a legal opinion from an attorney representing either of these entities.

I present the above as evidence of the charges I'll make: Nathan Cohen, Ph.D., aka Chip, N1IR, doesn't tell the truth. His threats to sue are pure fabrication. He claims he will send letters which he doesn't send.

He claims that a letter was sent which in fact was not. He claims he will institute lawsuits which he doesn't. And he presents statements of the illegality of my actions as fact which aren't backed by any evidence.

It makes me wonder how much of what else he says is fabricated. And how many of the other "facts" he presents are unsupported.

Roy Lewallen, W7EL

This is still a common-mode current, even though it is induced by the EM
field rather than being launched directly on to the outside of the coax
at the feedpoint.

>Couldn't this flow back down the
>coax (outter braid again) and be re-radiated, in the shack? Would a functioning
>RF ground stop this? Or doesn't it even happen?

Depends what you mean by "functioning". Yes, it does happen, and the
lower the RF impedance to ground is at the shack, the more easily those
currents will flow. That's what I was implying by "inviting" common-mode
currents. RFI is notoriously difficult to predict, and if you connect an
RF ground where you don't really need one, there is always a possibility
that it may make matters worse.

> for terrestrial radio circuits. Real world measurements match
> calculations to the decibel during normal propagation.

In the usual single reflection model typical of point to point UHF and microwave links, both the direct and reflected ray are usually considered to contained by the main lobe of both the transmit and receive antenna. The far field strength of each ray taken separately is equal to the free space antenna gain times the free space propagation loss. Calculation of the received power requires adding the voltage contribution from each ray propagating between the transmit and receive antennas.

Most point to point terrestrial paths are near grazing and the ground reflection coefficient will be very close to -1. A reflection coefficient of -1 means the reflection wave has the same field strength of the incident wave but undergoes a phase shift of 180 degrees.

The 'best' case is when the path length for the reflected wave is a half wavelength longer than the direct wave. The additional 180 degrees of phase shift compensates for the phase reversal at the reflection point and the two voltages add resulting in a received power of 6 dB greater than predicted by the free space formula.

The more typical case for amateur VHF and UHF point to point operation is such that the extra distance traversed by the reflected wave is much less than 1/4 wl and the two waves combine destructively and yield considerably less received power than predicted by the free space formula.

In the common case where the latter phenomenon dominates, the propagation loss will be proportional to 1/R^4 (-40 dB / decade in distance) as opposed to the free space loss proportional to 1/R^2 (-20 dB/ decade in distance). If the antennas are above the nearby clutter, the received power will be proportional to the product of the antenna heights squared and nearly independent of operating wavelength.

>
> Reflection at the path grazing point could affect signal levels.

It almost almost profoundly affects signal levels.

> To
> minimize this effect, the path is often engineered for 0.6 Fresnel zone

Unfortunately, hams usually can't even begin to get out of the first
null.

> The ringer is, of
> course, that a certain atmospheric refraction index is needed to produce
> the exact clearance, But the usual practices work very well anyway.

If the fade margin is sufficient to handle the idealized two ray
propagation model in the presence of bad weather, you've pretty well got
it made. Most real systems are a carefully engineered cost effective
compromise.

> electrical shock,

Which is provided by the AC housewiring, once you have determined it
to be properly installed.

> and a lightning ground, if you have ever heard of a
> lightning stroke where you live.

Here's the snag, and I'm surprised you'd offer that any 8 ft ground rod
will serve to isolate the ham gear from the house's AC grounding system.
Most of the damage I've seen over the years was from lightning either
going from a radio ground to the house wiring system **while enroute to
it's better quality ground**, or from the house's service wiring to the
radio ground, in every case *always* THROUGH the hooked-up equipment,
which suffers severly.
ANY lightning migigation effort that fails to consider the likely
effects of dual grounding systems and their nearly certain negative
effects on whatever gear is between is a failure, when lightning
actually strikes. I've seen the results many times, and that experience
is the root of my own treatment of my ham gear- Hook it to an antenna
and the AC mains *only* when it is being used, never when storms
threaten, and aways unhook when finished operating.

And I live where lightning is common. I've experienced many close
strikes (I live on a hill) but never had one that caused any damage to
my ham gear. One did come into the house on the power line, took out a
TV and a couple other small appliances, but my ham gear was untouched -
it was unplugged and ungrounded.

> The reason for a separate ground return to your common earth system is
> so your radio stuff doesn`t have to share the path to earth with other
> apparatus.

But it WILL NOT work that way, unless you go through a full lightning mitigation treatment process which virtually no ham station ever gets. Anything less is wishful thinking. Lightning will always search for the lowest impedance path to ground, and dual ground systems virtually assure that you will experience equipment damage from a strike, even if both are fairly good grounds. The strike will split and follow BOTH paths to final ground, creating havoc enroute.
The idea that a ground rod will protect your ham station from lightning is nonsense and I'm surprised you don't recognize that fact.

> That other apparatus or the wires connected to it could be
> the source of a huge abrupt current which could cause a proportionately
> huge voltage drop across the ground return impedance shared with your
> radio stuff.

Almost guarantreed. So then, what is the very best you can do to prevent lightning from going through your equipment, in one direction or the other, enrouote to what it sees as the lower impedance ground? Only one thing- UNHOOK it all, from both ground and AC.

> That could raise the voltage on your radio to a dangerous
> level. Your radio stuff deserves its own separate ground return wire.

Feel free. Mine doesn't deserve to be abused like that. I live in lightning country.

> It
> also works the other way. Your radio could be the source of a large
> surge which you would not want to endanger other apparatus or even the
> people near it.
>

Any ham who allows lightning to come into his home because he failed to reduce the liklihood to the maximum extent possible is irresponsible, and should review his situation carefully. Providing dual ground systems is NOT a good idea if you want to reduce the probability of a strike coming into your house- and this is not just my opinion, it's good engineering practice. Neither is allowing your amateur antenna feedline to be routed inside full time, and certainly not to remain hooked to radios 24/7. That's just asking for it. Once inside the house via an antenna cable the strike will search for a low impedence path to ground, and will almost surely find it via your house wiring-causing unnecessary damage and danger to the household, even when your rig is unhooked.

I once knew a ham who thought he was doing a good thing when he unhooked his antenna coax from the transciever when a storm approached. But he laid the connector end on the power supply cabinet (metal) and a light discharge from the antenna burned a spot on the cabinet - and ruined his rig as well as the power supply. He might as well have not bothered to unhook it at all. And Of Course he had his equipment grounded, and plugged into AC. If it had been unhooked and "floating" free it would have not been affected at all.

It doesn't take a full lightning strike to cause serious damage, static discharge from antennas is common, sometimes on windy days even without storms, and can easily damage radio gear.

BTW, this viewpoint was developed over some 40 years of close observation and much time spent in cleaning up lightning damaged radio gear which was necessarily powered up, hooked to antennas and working around the clock each and every day. Much was learned by observation of what was left behind following a strike. While complete mitigation procedures were not possible due to the "installed base" that could not be changed sufficiently without total reconsruction, I waa able to improve equipment survivablilty considerably.
My ham gear has no need to be hooked up and online unless I'm using it, so I protect it the best way possible-keep it out of the path of lightning and don't try to use it when storms are around the area. My body wouldn't benefit from being hooked to a "good ground" any more than my gear would when lightning strikes. The stuff is very dangerous and it's surprising that more radio hobbyists don't come into closer contact with it.

One more point- Lightning doesn't have to strike your antenna nor even the power wiring to cause damage to a rig that is hooked up. An induced voltage pulse from a close strike in your neighborhood can come from the house wiring or a hooked-up antenna to act as a transformer secondary winding, the strike path itself being the primary, for the very brief time of the strike, and raise voltage levels in gear that is hooked to the "secondary" to levels easily damaging to the gear.

"Even the very first fractal antenna article made a point of stating,
and showing, that log periodic antenna arrays are fractals,---."

My take is that Richard Clark said that log periodics were fractals.
Thank you for confirming that the world of fractals includes log
periodics.

Yesterday, Cecil showed that the elements of an array could be reformed
to each recreate a smaller image of the larger array. This would qualify
as fractal construction.

I hope I am slowly gaining a better understanding of what a fractal
might be.

Thanks for your contribution.

I didn't say that, Reg. RF current obeys Ohm's law. It flows toward the area of least resistance. There are a number of current paths to worry about with an antenna.

> Which way do you want it ? You cant have it both ways.

A balanced antenna does not guarantee balanced currents. The currents obey Ohm's law. Are you saying that common-mode currents are impossible with a balanced antenna fed with an unbalanced T-line?

> Assuming the generator is at the other end of the coax, take

An open circuit doesn't have a path to ground. An antenna does.

For anyone interested in the details, may I suggest a perusal of Chapter 21 in "Reflections" and/or "Baluns: What They Do And How They Do It" in the ARRL Antenna Compendium, vol. I?

Actually, Chip has done a great deal to retard the cause - if there is one - of fractally derived antennas. It's incomprehensible to me why a fellow who owns an antenna company would spend his time fighting with potential customers. He could be very well off if he'd move his company to Silicon Valley, develop some type of of "wireless solution for enhanced connectivity through fractal geometry", borrow huge amounts of money from entrepreneurs, do an IPO, and then sell out before it became obvious the company was never going to make any money. With his wealth, he could even do research and, hopefully, come up with something useful. Anything would get him more money, prestige, and attention than making an infinite number of objectionable little posts to this newsgroup.

Hi Roy,

Interesting litany of the absurd (for which there comes no great
surprise).

You forgot one particular milestone: that aggressive campaign to smear
you ENDED when I exposed the fraudulent statements made by the same
source vis-a-vis technologies that were patent pending.
The USPTO is unequivocal about the commission of a felony in falsely
claiming patent pending on technologies that have no claim coverage.

These claims were made by FAS as close to the patent publication as
one day prior. The patent process is one of complete disclosure, and
the review process guarantees that the petitioner cannot claim
ignorance of his coverage. To make such claims with the complete
knowledge that no such coverage existed is clearly a FRAUD
against our membership here.

from:
http://www.uspto.gov/web/offices/pac/doc/general/patpend.htm
>Some persons mark articles sold with the terms "Patent Applied For"
>or "Patent Pending." These phrases have no legal effect, but only
>give information that an application for patent has been filed in the
>Patent and Trademark Office. The protection afforded by a patent
>does not start until the actual grant of the patent. False use of these
>phrases or their equivalent is prohibited.

I believe I too was promised a love letter in the mail for having made this observation of persistent fraudulent statements (another fraudulent proclamation of having technology covered by pending patents was made yesterday).

I too, like Roy, have no actual expectation of ever hearing anything other than the fractstatic on this board. The moral and technical claims made by FAS have been prostituted to ego and debased long ago.

Thanks, Roy.

and lest we all forget:
DO NOT RESPOND TO TROLLS - ESPECIALLY FRAUDS

Richard Clark makes so many errors I do not pay attention to his--opinions--on issues of science and technology. I also note that he is in copyright violation over a file which I own, and has not placed nor been asked for permission to use. Thus I have serious issues not only with the accuracy of his statements but his ethical basis as well. The issue of copyright violation can,and will be treated with litigation unless he removes the file.

Log periodics have been identified and described as fractal antenna--arrays- for many years, although as far as I am aware, my description and articulation was the first, reported in the Summer issue of Comm Quart in 1995.

In 1996, at the IEEE APS Meeting, Dr. Raj Mittra gave an invited talk at Baltimore on FRACTAL ANTENNAS. This talk was about log periodic arrays.

In other words, it has been accepted as a convention to note that log periodoc arrays are fractal by antenna professionals. Whether radio amateurs accept this is not important; it is important that they be aware of it should they have an interest.

The reason why log peridioc arrays are frequency independent is that they are origin symmetric and self similar about a point. This was shown to be as a description of a closed-form description for the geometric requirements for frequency independent antennas , published in FRACTALS by Hohlfeld and Cohen in 1999.

Bart, WB6HQK wrote:
"If the fade margin is sufficient to handle the idealized two ray propagation model in the presence of bad weather, you have pretty well got it made."

That`s an impractical "if". Two components of a wave can cause a 6 db increase in signal strength, or a complete null. It depends on amplitude and phase of the two components.

No fade margin, however large, is big enough to overcome a complete null. Diversity and alternate routing are solutions to the "two ray propagation model". On long paths, there will be propagation outage (fades) unless you have diversity.

I will reiterate my point which was none of the above. Real world measurements match calculations to the decibel during normal propagation. Free space antenna gains are used in antenna system calculations. So, the antennas are proved to be operating as if they were in free space. This is because the antennas are being operated many wavelengths above ground, and the difference between free space operation, and operation very high above ground is insignificant.

My example had a rhombic 180 wavelengths above ground. It was at 3GHz, but operation would be the same for a 3-MHz rhombic 180 wavelengths above ground.

When does a rhombic in free space have its performance altered by the presence of the earth? When the earth is close enough to significantly alter the antenna`s characteristics.
This has nothing to do with how two rays from a distant reflection point interfere at a receiving location any more than the height of the ionosphere affects antenna gain.

Best regards, Richard Harrison, KB5WZI

Nathan:

Relax a bit. I read your statement the same way he did. It was the
"although" that messed up your intent and meaning.

Rewording as follows would work:

"As far as I am aware, I was the first to describe a log-periodic antenna as being a fractal. This was a number of years ago in an article I published in Comm Quart in 1995."

Everyone on this NG expects to be given the same level of respect that you would like to be given. When you start to approach people with that level of respect, they will give it back in turn. If you treat people with disrespect and arrogance, you will get flamed. Try a new appraoch for a few weeks and see what happens.

Dick Carroll said:
"The idea that a ground rod will protect your ham station from lightning is nonsense and I`m surprised you don`t recognize that fact."

Ground rods can be part of a protection system. I`m not so pessimistic as to say "you can`t protect against a direct hit". I worked many years in broadcast stations which operated right through countless direct hits without damage.

I used too many words in my posting. But, two words i did not put together were lightning and rod.

Should have said, use "star connections", not "daisy-chains".

I disconnect my stuff when I see a flash or hear thunder, if I remember.

Best regards, Richard Harrison, KB5WZI

Excuse Me;

Please do not impute me with attitudes that I do not feel, nor in any way represent. My 'approach' has always been consistent: you get what you give.

I am sorry, but I see nothing in my statement that in any way misleads or in any way says other than what was intended. If you are uncomfortable with that, then there is nothing I wish to do change it.How can I? I am a writer and that means that I have a certain style --which I have taken 30 years to nurture. I sincerely do not seek to abandon that which I have worked so hard to produce.

I cannot be responsible for the statements and misinteprations of others.

HOWEVER--

Others are responsible for THEIR statements, and I urge you to SET AN EXAMPLE in which individuals are not misrepresented; denigrated; libeled; and personally attacked. An example in which one does not hinge 'weighty' science issues through ignorance of wording such as: fractal; arbitrary; random.

Then we shall see if others will follow.

Cordially,

NC

Probably.

I found the sentence to be awkward and did not think that David's interpretation was inappropriate. Chip took offense and responded rather abruptly, as usual. I was simply offering to Chip that if he began to treat people with a bit more respect he might be pleasantly surprised as to how they react. Judging by his response to me, I think the message fell on deaf ears.

Yes, this is true, even in your case. That was my point. If you change
your approach and start to treat people with respect they might treat you
with respect as well.

Rather than simply acusing me of 'ignorance' (and you don't provoke anyone), engage me in a technical discussion:

What is your definition of a fractal antenna?

Are all self-similar antennas fractals?

Are all non self-similar antennas not fractals?

Please describe a non self-similar antenna (no loops) that is a fractal? Please give a technical reason why it is a fractal?

Do you believe that all loop antennas are fractals?

Please describe a non-fractal loop antenna, other than a simple circle, triangle or polygon?

What is wrong with calling the antennas I designed arbitrary or random? If I simply arrange wire in any shape of straight lines, why it is wrong to call this arbitrary? I used no math, formulas or self-similar concepts to create the shape.

Why are the arbitrary designs fractal? They are not self-similar, so what specifically makes them fractals? Please don't just tell me that they are. Give me a technical reason.

Answers here would be a good start.

1700. Butternut vertical on 6 meters

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-02 22:55:11 UTC
From: Larry Bratcher <lbratche@ipa.net>
Message-ID: <VdmM5.7992$Q92.137871@nntp2.onemain.com>
Source record: 177199

Is anyone using the 6 meter kit on their Butternut vertical? If so, please email me as I cannot get mine to resonate anywhere I put it. According to Bencher, the top bracket with the wire attached goes about 3/4 wave length above the ground (~162") and the other about 1/4 wave length below that (~54"). The instructions state 151" and 58" I believe. However, nothing close to this seems to work. The SWR is 5:1 + regardless. If anyone is successfully using the 6 meter on their Butternut I greatly like to know how it is set up.

Thanks

Larry

Well Well Have I opened another can of worms?
I always thought that the earth was an integral part of the radiating system in that a mirror image of the antenna was reflected in the earth. Hence the reason why stations on swampy land had better radiation or is this a myth too?
I know that the ELECTRICAL earth is for protection and all that, but I thought the earth from your rig was part of the antenna/earth system for the performance of the antenna. If I was confused before, now I am utterly dumfounded.
Thanks anyway for the responses.

Steve- please don't hold your breath while waiting for an answer. He will not answer, and he will give one of several excuses, if past history is a clue.
1. (most likely) he will say they even a rudimentary search will show the answers, so Why should he do your homework for you?
2. He will claim to have published this in a paper, and he has a policy of not repeating himself.
3. He will make snide comments re your education, or lack thereof. (interesting side note- you frequently give his honorary title, Dr., but I do not recall him ever doing so when you are being referenced. ? why?)
4. To give an answer will prematurely divulge material germane to a pending patent.
5. He will ignore the questions (although this is at least the second posting). He cannot claim he did not see them , because the record will also show that he reads EVERY post here, FAST. Never-the-less, this has an unknown probability, also.

THere are more, according to past record, but he can, and probably will, use one of these.

1705. Re: Earthing

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-02 23:16:56 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A01F5E8.3571E1F9@eznec.com>
Source record: 177204

The "mirror image" is a reasonable concept when dealing with horizontal antennas and moderate to low radiation angles. But for horizontally polarized waves at very high angles, like the ones used for NVIS communication, the reflection is more complex. And for vertically polarized waves, the "mirror" idea is pretty seriously in error. It's the interference between the direct ray and the ground reflection that produces the vertical radiation pattern of an antenna. You'll find that the pattern of a horizontal antenna over perfectly conductive ground (a true "mirror image" effect) looks almost the same as over ordinary dirt, at least at all but high angles. But this isn't at all true for verticals. Because of the nature of the ground reflection, the very low angle radiation from a vertical is highly attenuated unless the reflection occurs from very highly conductive ground. Salt water definitely is in this category, and a swamp probably is. So a vertical on swampy land will likely produce very strong low angle radiation, while one on ordinary ground won't. (The ground wave will also be attenuated less over swampy regions, but this is of interest mostly to AM broadcasters.)

It's an interesting subject. You can see the sky wave effects for yourself in graphical detail with the free EZNEC demo program available from http://eznec.com. If you use MININEC type ground for verticals, losses due to ground system currents are ignored, and the changes you see in the pattern as you change the ground characteristics are due solely to the changing ground reflection. For horizontal antennas lower than about 0.2 wavelength, you should use the High Accuracy ground model; above that height, all three ground models will produce similar results.

> Why are the arbitrary designs fractal?

They can be (not must be) fractals in the same way shorelines and clouds are fractals. Clouds are not random - they obey certain boundary conditions. A simgle wire cannot be random since each point is connected to an adjacent point - that's a boundary condition. My personal opinion is that if no other type of loading is allowed other than simple folding, a fractal will turn out to be the most efficient design for a given volume. The folding method that causes the least undesired interference in the far field is, IMO, likely to result in a fractal.

Larry,

I had to shorten the length of the stub a bit more than they indicated.

I meant to take measurements when I was done. I'm guessing that
the antenna adjustment is sensitive to ground efficiency. Mine did
come in (~<2:1) with some adjustment with a bendwidth of about
1 Mhz.

Simple fact is that Gore never said he invented the internet. He did,
however, take the lead in his efforts to pass legislation that would
create what is now known as the internet. Arpanet was NOT the
internet. It was a network of a few handfulls of universities and
think-tanks. By NO MEANS was it the internet.

I did have several computers in that time frame and I DO remember that
there were computer professionals that balked at the notion of home

computers.

Schools had computers...mainly Apple II computers. They were usually
the ONLY personal computer many people had contact with.

The internet as it is commonly knows did NOT exist in the sixties.
Arpanet existed and it was no more the internet than the horse and
buggy was an automobile. Do some research on Arpanet before you spew
this dribble.

Ed Hare, W1RFI wrote:
"Here is the pattern of a half-wave dipole up 180 wavelengths on 20 meters."

I suspect Ed used a computer model to plot the vertical pattern. The results would result from summation of the direct and reflected waves,

Located 180 wavelengths above a reflecting surface, the downward traveling wave has spread so that its strength at the reflection point is at least 65db less than the direct radiation from the wire.

I understand that the pattern will not show downward radiation because the earth blocks further travel and will absorb (my 3GHz if it`s the usual soil) or reflect in the case of an assumed perfect earth, the energy which strikes it.

I don`t understand how a reflection so attenuated by its space travel could make such a hole above the wire in the vertical radiation pattern of the dipole. To create a complete null requires equal and oppositely phased signals.

Best regards, Richard Harrison, KB5WZI

Cecil, W6RCA wrote:
"---the gain in the highest gain lobe goes up while the take off angle for that lobe goes down."

True, as the height of the dipole increases above 1/2-wavelength, it happens as Cecil says. There is a downside. The main lobe narrows as its gain increases and that reduces the range of useful vertical angles. At the same time a new take off angle appears which is straight up, or 90 degrees. This is mostly good for nothing and robs power from useful angles.

Best regards, Richard Harrison, KB5WZI

My 5 band quad is at a boom hieght of 35 feet. On 20 meters the tuning changes when I rotate it 90 degrees. I attribute this to the Aluminum siding on the building that the tower is bracketed to. I could not get the tuning right on the bottom two bands, although it does work. The 20 meter element is about 9 feet above the roof. Given a choice I would make it higher.

If you use a choke to force a minimum in the common-mode current at the place where it "wanted" to be maximum, the new current distribution will generally be less favorable for radiation, and the new current maximum will be smaller than it was.

Taking the process one step further, two chokes spaced about a quarter-wavelength apart can be quite effective in getting rid of common-mode currents in that part of the line. As Reg says, it will pop up somewhere else instead (if the rest of the line is long enough). After fitting the first choke at the "natural" current maximum, the rest of the process can be rather like squeezing a long balloon - as confirmed by both modeling and practical experience.

>I would rather have amps in the shack than volts - they are
>less painful.

That's true, but it can often be difficult to predict which you're going to get. A clip-on RF current meter is a very valuable tool to confirm (even in an uncalibrated way) whether things are getting better or worse.

I have some interest in using an Alpha Delta Outpost with an Outbacker that I am very happy with for mobile use. Does anyone or has anyone used this device and what did/do you think of it? I currently am using a Cushcraft R7000 and am not happy with the domestic perfomance. DX is fine. Could be the takeoff angle is blowing me out of the water here in the states. I would like to use a tower and beam but like a vast majority of amateurs I have to accept compromises. The Outbacker has performed well on my vehicle. I can consistently work VK's while mobile so I know the Outbacker is capable with a proper grounding system aka. Ford Expedition.

Please answer here or direct via n8mg@arrl.net

> --
> Alan
> WA4SCA

Hi Alan,

Well there are trade offs to both.. however it will depende much on your surroundings.. If you have a fairly clear flat shot.. few trees or manmade structures in the are out to a couple wavelengths at the lowest Freq. you should do very well with the ground mounted vertical.. and a good radial system. I recomend at least 32 at the lowest frequency of operation. no need to make them exactly resonant either.. (32 is a compromise but what you'll gain after that point is minimal for the effort and cost involved.)

If on the other hand you are in a typical suburnban subdivision i'd opt for the roof mounting mode..

Hope this Helps 73

I don't know at what distance NEC calculates the far field pattern, but in
the far field, the direct ray and the reflected ray have travelled
approximately the same distance so they could well be at an equal and
opposite polarity at a point very far away from the antenna.

>When you start to approach people with that level of respect, they will give it back in turn.<

Chip's been receiving this oft-repeated sage advice for a long time. Historically, the NG has responded to his "unique personal style" with all manor of concern ranging from respectful coaching to ferocious flaming. To no avail!

In my view, the outcome is predestined to be uninfluenced by us. Like chess master Gary Kasparov, I'm betting Chip will snort, posture, and bully his way until the very end--when, as some have claim for Kasparov, aliens ultimately arrived to steal his brain.

Only Chip can alter this course. If he does not, remedy will likely come in response to a 911 call initiated by a concerned friend or family member rather than as a ruling in Civil Court against a fellow ham.

Nope, just that the most efficient ones will turn out to
be fractals. If you had a program that put a certain length
of wire in a certain volume and iterated it until maximum
radiation efficiency was reached, I think the end result
would be a fractal.

I imagine I could, but frankly, I woldn't answer this of ANY antenna professional, because to me it indicates they just haven't bothered to do the basic research needed.

I would NEVER insult a colleague by asking things that I truly need to look up for myself--and I am not offended wheninadvertantly and on the rare occasion, they have suggested I do so.

Why must the positioning on this NG be to:

1) describe someone as mentally ill;
2) try to get them fired;
3) pose the 'solution' as insanity, death, or a reckless act??

These things are SO UNLIKE what I am, that it becomes unfathomable for me to imagine individuals who cannot support even a modest level of human decency.

Only one problem- he can't give them because he doesn't have them!

1741. Use of diode in antenna switch?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-03 02:07:32 UTC
From: Swler <swler73s@yahoo.com>
Message-ID: <3A021DE4.2513A06D@yahoo.com>
Source record: 177070

I want to construct an antenna switch box. To prevent back signal flow I
was thinking about using diodes.
Will a diode cause any signal loss?
Any suggestions or type of diode to use?
Thanks.

Only for the types of antennas that require this for completion of the
signal return.(as in ground mounted verticals) And then, you'd better
improve on the conductivity of the earth in question with a metallic
ground plane if you desire decent efficiency.
If earth ground is so necessary to radio transmitters, what do
aircraft do at altitude?? To say nothing of sattelites in space.....

Hence the
> reason why stations on swampy land had better radiation or is this a myth
> too?

Not at all...the action of the earth upon the launched wave is a
separate matter entirely from any necessity of grounding your
transmitter to a rod stuck in the earth.

Source record: 177074

Dear -EDDY-
Many AM receivers are able to demodulate, after a fashion, FM
signals. So called "slope detection" is used. The idea is to place
the FM signal's center frequency on the slope (edge) of the AM
receiver's passband. If the edges of the passband are too steep or
the FM signal's deviation too wide, there will be a lot of
distortion. Also, the FM signal must be strong for this to work.
Used this scheme to identify FM broadcast stations I used as test
signals for a study of VHF propagation in the "hills" of West Virginia
- the signal strength "meter" did not have an FM detector.
Regards, Mac

> --
================================

At last you've got it ! The choke is not needed at the high impedance point.

Unfortunately, when it is placed at a current maximum the current maximum just shifts itself 1/4-wavelength along the line.

When the common mode stuff is picked up by radiation from the antenna there's no way of getting rid of it. It can only be relocated somewhere else and swept under the carpet where it won't be noticed.

I would rather have amps in the shack than volts - they are less painful.

Reg.

> as you so delicately put it.

Well, my friend, if you think asking a question is an attempt to
"demean" something, then you truly have a twisted sense of the word.
Look, I have no problem with anyone maintaining a connection with their
ancestry or their motherland. However, the message talked about
celebrating the anniversary of an organization, not their homeland or
their ancestry. So, I just wondered out loud if the goal was to
maintain a connection with their motherland, or to maintain a connection
to this organization.

To get back to the specific issue raised (the special permit), if the
goal is to maintain a connection to this organization (a business with
no legal, or non-profit, status in Canada), then I can certainly
understand why no special permit was issued. Of course, that seems so
obvious in light of the opening message, I didn't think I had to spell
it out for people. But, obviously some people are not able to see the obvious.

So, Gore said that he "took the initiative in creating the Internet" as opposed to inventing it. That is a really fine line to draw since both words have almost the exact same meaning.

Of course, one has to wonder if the author (Lars Erik Nelson) even has the quote right since so many other things in his article were wrong. For example, he said that, "In March 1986, when computers were still something found mostly in laboratories, Gore sponsored..."

Of course, by 1986, computers had been available to use in the home for almost ten years, and personal computers in the home outnumbered laboratory computers by almost twenty to one (heck, in 1986, I had two of them in my house).

He went further to say that three years later (1989 - a timeline he gave when talking about Minitel), "even computer professionals were jeering at the notion of personal computers. They would be a waste of money, costly machines for balancing checkbooks or storing recipes."

Of course, we all know that is not the case - by 1989 no computer professional was dismissing personal computers as a "waste of money, costly machines for balancing checkbooks or storing recipes." By 1989, most companies in America were in the process of updating their workplace to include personal computers. And many schools even had computers available in the classrooms by 1989.

But, in any case, regardless of what Gore did or said in the 1980's, the internet has existed in some form since the mid-sixties, twenty years before Gore claimed he "took the initiative in creating" it.

Hi Steve,

No luck hmm?

The subject: a technical question in a technical forum
response: no answer for the forum because you are a professional (as
if we had any doubt).

The reductio ad absurdum would be that the forum will never get these
answers until you professionals quit this forum - but this also means
the HMFIC of FAS being a professional (ah yes, here the doubts arise)
leaves too. Still no answer for the forum.

The logic thus begs the question: why raise the topic of fractals if
you won't talk about it?

Makes for perfect opportunity to advertise specifications, offer
testimonials and beg off answers because of wicked merchants
eavesdropping to steal the latest trade secret. :->

And what became of
>RESULTS: POSTED ON this NG by 1 Nov 2000. In the event of no-winners, the
>closest value and design will be announced on this NG at that time.
or was the pairing of the following date too strained?
>Nathan Cohen has his position terminated on 1 Nov.

Steve, your six winners seemed to have upset the order of the
universe. The Forbidden City has fallen to the Barbarians.

Hi OM,

If you are speaking of diode logic for relay control, use any diode capable of a forward current at least twice the current demand of the relay.

On the other hand, it looks like you are talking about signal steering diodes. This is considerably more complex than text can adequately reveal. The situation here is that the diode needs to be biased on or off to serve the purpose I suspect you wish to achieve.

That is, serve as a switch. Here the principle determiner of diode selection is the current flowing through it. This is a function of both signal current and control current. At a minimum this means the diode must support double what your source provides.

Look into high power VFETs. Siliconix is a good house.

Hi EDDY,

The answer to your first question is yes.

AM receivers tuned off frequency of the FM signal will pick up a very
weak, but readable signal. This particular characteristic is called
slope demodulation. This is the only simple way to answer yes.

Gerry, what does the owner's manual for your radio say about grounding? For example, my Yaesu's manual says the following...

The provision of an effective grounding system is important in any successful communications station. A good ground system can contribute to station efficiency in a number of ways:

- It can minimize the possibility of electrical shock to the operator.
- It can minimize RF currents flowing on the shield of the coaxial cable and the chassis of the transceiver which may cause interference to nearby home entertainment devices or laboratory test equipment.
- It can minimize the possibility of erratic transceiver operation caused by RF feedback or improper current flow through logic devices.
- It can minimize the effects of an unexpected lightning strike on the antenna structure.

The manual then goes on to explain some of the common ways to obtain an effective grounding system (ground rods, cable installation, etc).

Now, we can talk about the technical aspects of grounding systems all day long, but in the end it comes down to one thing - it can't hurt and it might even help. So, because of that, I always recommend a ground system for every installation unless there is a very good reason not to have one.

I believe Den is right. Last week at Hamfest Iowa WB0W was selling the
259B for $204. I just checked their web site, http://www.wb0w.com/ and
they have it listed there for $199.95.

Hi Cam:

What geometry of 1/2 WL of wire bent into a fractal shape is more efficient
than a 1/2
WL dipole?

Chip, you remain true to form. Although I am disappointed, this is exactly
the response I expected.

What I don't understand is the following: You frequently post to this NG
very broad generalizations regarding the 'benefits' of fractal antennas, the
$1000 fractal challenge, announcements of your fractal patent allowances,
numerous statements of your superior knowledge base and skill, etc. You
seem to have all kinds of time for these posts and the copyright
infringement claims. Yet, when someone asks you very direct technical
questions on fractal antennas and fractal geometry you avoid the discussion
at any cost, declaring that the person should go look up the information for
themselves. In doing this, you lose all credibility. If you are not
willing to really discuss any of this in detail, you have no business
bringing up the topic of fractal antennas on this newsgroup.

What I find most appalling is the following:

1) You take Kraus's Small Loop Approximation out of its intended context
and then declare it to be "INCORRECT". At best, your claim is based on a
lack of technical knowledge and understanding; blind arrogance; or at worst,
pure fraud. (I don't believe you are fraudulant) You can declare Kraus to
be "INCORRECT", yet you refuse to
discuss your own technical claims regarding fractal geometry.

2) In discussing my designs, you claim that I "have made a scientifically untenable statement"; that I have made statements that are "both profoundly ignorant in the use of proper wording, and the results, don't support anything"; that in this subject I am "at best, a beginner at this time"; that I am spreading "misinformation and propaganda"; and that you are someone who "obviously has a greater knowledge base". If you are inclined to make statements like this, its appalling that you refuse to answer my questions and support your claims.

Probably about as good as anything I guess. Try to get over metal as
much as you can. Also as high as you can get it. If clamped to the
ladder, make sure the ladder is grounded real well. MK

Reg, you seem to be under the impression that we are electing the next Head of Global Socialism. Most of us in the US are not supporters of socialism and in particular on a global scale. The effect of a US President on this country can be substantial and that is what most Americans are concerned with. If we had wanted a socialist society and all that comes with it, our ancestors would have stayed in their country of origin. BTW, if you remember, the majority of the founders of this country were English.

Not in my system it doesn't. I vary the length of the ladder-
line until the current maximum point is located at the choke.

> When the common mode stuff is picked up by radiation from
> the antenna there's no way of getting rid of it.

I've been talking primarily about conducted common-mode
currents. Good engineering practice can usually solve the
inducted common-mode problem.

Source record: 177093

I'm considering putting up a tower and either a mono-band 20 meter yagi, or a quad. My question concerns the decision about how tall a tower to buy. Would there be much difference between say a 35 foot tower and perhaps a 54 foot tower in terms of ability to hear signals better and to be heard? The only thing I've seen in print concerning this question was that a yagi should be approximately one wavelength off the ground to avoid interaction with the ground? Does that sound right? Tom

We're talking about folded, limited-space antennas that occupy a small
volume/area, not full sized antennas. A 1/2WL long dipole is not folded.

For example: If the volume allowed for the 1/2WL dipole is
1/8WLx1/8WLx1/8WL, the most efficient folding into that volume
will probably be a fractal. Attic antennas would be good examples
of limited space antennas. And of course, folding does not compete
very well with discrete components.

I've seen the phenomenon you describe -- of the feedline current distribution changing in response to a balun -- in modeling of a ground plane antenna. Putting a second balun about a quarter wavelength from the first reduces the current a great deal in this model. I haven't confirmed it by measuring a real antenna, but would be surprised if the program wasn't quite accurate in this situation.

Jim,

I want to remind you that we are about to experiience the anniversary of Kristallnacht. If you don't know what that is, you should.

You should also be aware that Goebbels arranged it so that the German Jews were themselves blamed for Kristallnacht.

I hope you will appreciate that this is the same kind of propaganda I see here.

Hi Jim,

You need only review the operations and controlling interests of the Bush boys in their Savings and Loan period during that time in Texas.

The Bush name is all over some of those "failings" that we pulled out to secure Grandmother's investment. The Boys made money playing with that money, loaning it out to their friends, lost it, took the tax break and then pleaded for a government bailout so they would not have to cover the losses of their poor judgement.

That paper trail has been around for years and was even discussed during that time (but was overwhelmed with Iran-Contra shenanigans in the headlines).

This is why Jeb is not running and W. is. Jeb's fingerprints are all over the mess, but blood is thicker than water and W. will take care of family in due time. So will you with your tax dollars going to them to rescue their "losses" - again.

From: Joe Schlatter <joe@schlatter.org>
Message-ID: <3a076b69@news.planetc.com>
Source record: 176971

Please do not view my comments as flaming -- get the Rohn engineering data, follow it to the letter, if you have questions, contact Rohn. Do not rely on the experiences of folks on the newsgroup, some of whom may tell you "Dig a hole until it looks big enough and fill it with concrete." When the whole thing crashes down, taking a big piece of your roof, your wife's car, and your neighbor's brand new SUV, the insurance company will deny your claim based on Rohn's figures, not on what Good Ol' Boy Engineering told you.

You can work the world on any old piece of wire fed with any old piece of cable. You can work DX with a one-transistor rig. It's fine to experiment with wires and flea power but when it comes to a tower, everything must be strictly professional or someone will get killed.

Andrew,
Using wire, or any other conductor, as supports may lead to
a problem, but it may not. (thats a 'help', isn't it?) If you
keep the support cable/wire's length away from multiples of a
1/4 wave on the band(s) you use, you should have no big problems
with it. Go ahead and use it, see what happens.
Changing conductor size between feed line and antenna makes
very little difference in this case, don't worry about it. there
will be an impedance mismatch between antenna and feed line, but
that's something else that just doesn't matter in this case, and
the antenna/feed line will handle any power you can put into it.
If there's a problem because of power, it will be at the tuner
you use for matching, in the station. If the tuner is rated for
twice the power your transmitting, you should have no problem
with the system. (Most amateur tuners are rated in 'PEP', so
use a tuner that is at least twice the maximum power of what
your going to feed it).
It doesn't matter how it goes in the morning... let us know
what happens!!
'Doc

1775. Re: Tower Height

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-06 00:00:00 UTC
From: Chuck O'Neal <coneal@ultranet.com>
Message-ID: <8u80s9$al5$1@bob.news.rcn.net>
Source record: 176974

It depends upon what you want to do. For US
only QSO's, perhaps 35 ft would be OK, giving you
a radiation anlge of 28 deg or so. For any reasonable DX,
you will want a radiation angle of 15 deg or lower, which means
1 wavelength above ground, 70 ft or higher.

As you go higher in freq., the angle drops for the same path length,
giving about the same requirement for 10M in terms of absolute height above
as for 20M. With a yagi or other end fire array like a log periodic, one
must multiply
the array factor against the ground reflection factor, giving you
the total pattern. At heights over 1/2 wave above ground, the array factor
for any endfire antenna with reasonable gain will surpress higher
radiation angles, less useful for for DX. Stacking is even better, that's
why we do it.

Bottom line, "It's the angle of radiation for a desired path" that
determines the ideal height.
This will vary, dependent upon time of day, solar flux, time of year, K
index, ect....
But...the good news is that on the average, I would say that 70 ft is about
the best compromise,
unless you are in the middle of the US and then I'd say at least 90 ft., for
DX that is....

1776. WTB:ATV Filter for 900MHZ and 1253MHZ

Newsgroup: rec.radio.amateur.antenna

Lots to see and do.....here are a few features

1. Live DX cluster telnet links - Try them out! - on The DX Page
2. Online DX Logbook - on The DX Page
3. Many station and equipment photos
4. Several photos of Prescott,Arizona USA
5. Post a public link to your site on the Free-For-All Links Page

Plus lots more....including Guestbook,Station Description,3D Art Gallery and
Music Page with free downloads....

This life and death subject has no room for antidotal experiences.
Please obtain the necessary specifications and requirements directly
from Rohn, POBox 2000, Peoria, Il 61656 (309)697-4400. For example,
the allowable antenna area for a 30ft self-supporting 25G tower
exposed to ice and 90mph winds is ZERO.

You spout unsubstantiated facts, and yet demand others post references to things we have all been witness to. Is the press more adapt at understanding the English language than many of the observers on this newsgroup? I think not.

You would have made a good Maoist with your ability to follow the party line to the letter without question. You may be right on some of your issues, but!, your inability to even concede the known facts dos much to harm any credibility you may have had at any point in your life.

After tomorrow, I suspect you will be singing the theme from M*A*S*H.

Source record: 177027

I think that Mike Traffie doesn't intentionally mis-state his gain numbers. It's my understanding that he has measured the gain figures that he states. Anyone who wants to argue the point with him can reach him easily by dialing the 800 number listed in the Hexbeam ad in QST. I don't get too concerned about the gain figures that beam manufacturer's give. In the past, all of them have stretched things a bit, that's why QST stopped publishing the claimed numbers decades ago.

What I know for sure is that the Hexbeam works very well indeed, and the operating bandwidth is far in excess of anything else I've seen. The variations in gain and f/b ratio across the bands has been covered elsewhere - I believe W4RNA has some modeling info on the various compact wire beams at his website.

>the allowable antenna area for a 30ft self-supporting 25G tower
>exposed to ice and 90mph winds is ZERO.

I agree that the Rohn specs & requirements should be followed.
I have been to the Rohn website (www.rohn.net) and have sent an email
to them detailing my plans and seeking their recommended base size.

However, I am still interested in knowing what others have done.
Problems, etc that others have run into. The group I run with tends
to "over-engineer." Can a base ever be "too-big?"

Simply because a person has been arrested does not preclude them from anything. If you look closely at those forms that ask the question, they ask if you have ever been CONVICTED of a crime. Anybody can be arrested for anything, but unless and until they go before a court of law and have a trial and are found guilty, they remain an innocent person.

There is a very big difference between an arrest and a conviction. That is why a persons' arrest record is not public information, it would only become public record if they went to trial and were convicted of the crime they were arrested for.

A CCW, a loan for a house, an employment application, etc. asks about convictions. Admitting you are guilty of a traffic violation (which was what a DWI was classified as at the time of GW's incident) and paying the fine does not mean you were convicted of a crime. If it did, then the vast majority of persons who drive a car would be classified as criminals.

You are incorrct Dan. GW Bush WAS convicted of the crime. He plead
guilty and paid the fine. When you plead guilty, you may not have to
go before a judge, but you ARE convicted of the crime.

Dan is not incorrect just because you happen to disagree with him, Ran.
Usually a distinction is made between a felonious conviction and a
misdemeanor.

Bryan,
If I remember correctly, Rohn 25g can be un-guyed up to
50 feet. I also think that encludes an 'eave' brace on a
house. It just depends on what you 'hang' on the tower.
As to how large the base/pier should be, going slightly
larger than what Rohn recommends won't hurt a bit. doing
it 'right' the first time is always better than re-doing it.
'Doc

Over-engineering in this case is good. Get the Rohn data and follow it.
Wind loading changes with geographical area as well, what works in
central Maine may not last in the Texas Gulf.

John Burke Burnett wrote:
"We are investigating how to set up a simple, low-cost, yet effective radio network---."
"---Local regulations require use of 27 MHz band frequency for CBs."

You`ve answered the question already. CBs on 27 MHz are the cheapest and most available radios in the world. They should easily do the job using available towers and hi-gain antennas to span 60 kilometers. All you need is line-of-sight clearance. In flat terrain, you`d need about 200 feet elevation on each end of the r-f path. For extra help, plenty of (illegal in the USA) high-power amplifiers are available.

FM repeater systems operating in the low-VHF range (30-50MHz) would be better, and could be strung together in a chain of repeaters with low towers, but would be much more expensive and perhaps not allowed anyway. Unmanned repeaters may be subject to theft and vandalism too. SSB is an unnecessary complication unless you are using high capacity multichannel radios.

H-F radios can be used at much more cost. I`ve replaced a troublesome SSB h-f link working on a 40-mile path with a low-band VHF link which gave much better results (and we really didn`t care about the cost), and it cost less than the SSB.

Best regards, Richard harrison, KB5WZI

Note that I specifically said, "arrested and pleading guilty". What is it
about "pleading guilty" that you do not understand? Pleading guilty is,
by definition, the same as being CONVICTED of a crime.

> There is a very big difference between an arrest and a conviction.

Not if one pleads guilty, as George W. *allegedly* did. A guilty plea
is the same as a conviction.

> Admitting you are guilty of a traffic violation (which was what
> a DWI was classified as at the time of GW's incident) and paying the fine
> does not mean you were convicted of a crime.

If you pay the fine, then you are, by definition, guilty. Are you saying that
pleading guilty to a DWI is not a felony in Maine?

Sorry Richard, a graduated income tax is a redistribution of wealth.
By no stretch of the imagination can reducing taxes be construed to
be a redistribution of wealth. In fact, reducing taxes is the exact
opposite of a redistribution of wealth. If the tax rate was ZERO,
there would be, by definition, NO redistribution of wealth.

Floyd Sense wrote:
> I think that Mike Traffie doesn't intentionally mis-state his gain numbers.

If 10dB over a dipole at the same height is not intentionally mis-stating
his gain numbers, then I don't know what is. It is impossible for a two-
element beam to have a 10dB gain over a dipole at the same height.
To maintain such is simply a lie and hams should be told who is engaging
in false advertising. The mealy-mouthing saying that customers have
reported 10dB gain over a dipole at the same height is snake oil tactics.
If customers actually knew the definition of 10 dB, they wouldn't show
their ignorance by making such claims.

The HEXBEAM is a good antenna that can stand on its own merits. Why must
the manufacturer lie about its merits?

Dear Friend,=20

This letter is about an opportunity to make an incredible amount of =
Money (CASH !!!) in a very short time. The cost is only $6.00! Give it =
a try! All I did was follow the instructions in the letter that I =
received below. Here is a testimony from one of the thousands who have =
benefited from this simple investment plan.=20

"I'm a retired attorney, and about a year ago a man came to me with a =
letter. The letter he brought to me is the same letter before you now . =
He asked me to verify that this letter was legal. I told him that I =
would review it and get back to him. When I first read the letter, I =
thought it was some off the wall idea to make money. A week later I met =
again with my client to discuss the issue. I told him that the letter =
will be all right. I was curious about the letter, so he told me how it =
worked. I thought it was a long shot, so I decided against =
participating. Before my client left, I asked him to keep me updated as =
to his results. About two months later he called me to tell me that he =
had received more than $800,000.00 in cash! I didn't believe him so he =
asked me to try the plan and see for myself. "=20

"I thought about it for a few days and decided that there was not much =
to lose. I followed the instructions exactly and mailed out 200 letters. =
Sure enough the money started coming in! It came slowly at first, but =
after three weeks I was getting more than I could open in a day. After =
three months the money stopped coming. I kept a precise record of my =
earnings and at the end it totaled $868,439.00. I earn a good living as =
an attorney, but as anyone in the legal profession will tell you, there =
is a lot of stress that comes with the territory. I decided if things =
worked out, I would retire from practice and play golf. This time I sent =
out 500 letters. Well, three months later, I had totaled $2,344,178.00." =

"I met my old client for lunch to find out exactly how it works. He told =
me that there were a few similar letters going around. What made this =
one different is the fact that there were six names on the letter, not =
three like most others. That act alone resulted in more returns. The =
other factor was the advice I gave him in making sure the whole thing =
was perfectly legal, since no one wants to risk doing anything illegal. =
I bet now you are curious about what little changes I told him to make. =

Well, if you send a letter like this one out, to be legal, you must sell = something if you expect to received a dollar. I told him that anyone = sending a dollar must received something in RETURN. So when you send a = dollar to each of the six names on the list, you must include a slip of = paper saying , "Please add me to your mailing list" and include your = name and mailing address. This is the key to the program. The item you = will received for your dollar sent, is THIS letter and the right to earn = thousands."=20

Follow the simple instructions EXACTLY, and in less than three months = you should receive MORE THAN $800,000.00 IN COLD HARD CASH!=20

1) IMMEDIATELY send $1.00 (US$) to each of the six people listed below. = THE SOONER YOU SEND THE "$1.00 LETTERS" THE SOONER YOU CAN START GETTING = A RETURN! Wrap the dollar in a note saying "PLEASE ADD ME TO YOUR = MAILING LIST".=20

1. C. Kolytiris 1312 4th Ave Seattle, WA 98101=20

2. Steve Werden 13625 55th dr se Everett, WA 98208=20

3. Chris Mcelhany 221 W. Mercer Apt #303 Seattle, WA 98119=20

4. Holly Ellingson 1451 E. Republican St. Apt #4 Seattle, WA 98112=20

5. J. Burke 22 Heron Place Rexford, NY 12148=20

6.Nicholas Gebhardt W1956 Crampton Rd. Warrens, WI 54666

2) REMOVE the NAME and ADDRESS NEXT to #1 at the top of the list and = move the rest of the names UP one position. Then place YOUR name in the = #6 spot. This is best done by saving this to a file and entering your = information on line #6. Be careful when you type the addresses. Don't = forget to PROOFREAD them. Make SURE that the names and addresses are = correct.=20

3) When you have COMPLETED the above instructions, you have several = options on how you market the letter - through the Postal Service, = through E-mail, through posting in "FREE CLASSIFIED ADS" and = "NEWSGROUPS" ON THE INTERNET, or through whatever way you think is most = effective. To send this letter out to thousands of people and increase = your profits, I suggest you use a Bulk E-mail company. They are fast, = effective and give excellent service. This letter has been proven = perfectly legal for all of the above as long as you follow the = instructions, because you are purchasing membership in our exclusive = mailing list. The more you send out, the more YOU will make. We strongly = encourage you to mail this letter to family, friends, and relatives as = well.=20

THIS IS A SERVICE AND IS 100% LEGAL. (Refer to title 18, section 1302 = &1341 of the US Postal and Lottery Laws) Assume for example you get a 8% = return rate.=20

1) When you mail out 200 letters, ONLY 16 people send you $1.00=20

2) Those 16 people mail out 200 letters, (3200 letters) and ONLY 256 = people send you $1.00=20

3) Those 256 people mail out 200 letters, (51,200 letters) and ONLY 4 , = 096 people send you $1.00=20

4) Those 4,096 people mail out 200 letters (812,200 letter) and ONLY = 65,536 people send you $1.00=20

5) Those 69,536 people mail out 200 letters (13,107,200 letters) and = ONLY 1,048,576 people send you $1.00.

At the Next level your name -drops off the list. Think about it. Look = what you WILL have BEFORE your name-drops off the list! I know this = looks and sounds unbelievable. Just try it, and you will be happy that = you did because you will received proof when THOUSANDS of ONE-DOLLAR = BILLS start to pile up!=20

***MAKE SURE you send One US dollar to each of the six names on the = list. (This is VERY IMPORTANT), with a note saying "PLEASE ADD ME TO = YOUR MAILING LIST"=20

P.S. You've read this far, so let me as you one simple question, WHAT = HAVE YOU GOT TO LOSE? Even with a 1% return you will still get = $100,000.00 in 90 DAYS!!! What you can gain is an income, like the = example in this letter. You will have a very small expense, but you will = reap HUGE potential returns. What do you have to lose? I invite you to = JOIN our mailing list RIGHT NOW!=20

Thanks you for your time. GOOD LUCK & BEST WISHES TO YOU !!!=20

24 years ago a DWI in Maine was classified as an infraction - a violation of the vehicle code. It was neither a misdemeanor nor a felony, therefore not a crime, therefore not a criminal act. To call it a crime by today's standard of definition would be considered "ex post facto" law, which is forbidden by the courts.

You might want to do some legal research so as to gain a better understanding of the differences between infraction, misdemeanor, and felony classifications.

1808. 160M Dipole Hoist/Anchor Question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-06 00:00:00 UTC
From: cathexis@erols.com
Message-ID: <3a073912.32224990@news.erols.com>
Source record: 177051

Greetings,

Well, thx. for all your help so far. Here's where I stand right now.
I've got the dipole assembled and spread-eagle out in the back yard.
Turns out I did find 100ft. of 450ohm ladderline at HRO for 19.95 so I
bought a spool. This is very well soldered to the two legs each 125ft.
in length (plus 1 ft. for wrapping the egg insulators). A drilled center block
of good strong Beech wood is the center/anchor point. All laid out and
ready to hoist in the am.

My question is: Will using more 14AWG insulated for the hoist/
anchor points on center and ends mess me up? That is, will it cause
appreciable interference or really louse up my ability to send and recieve
well? Bear in mind this dipole is gonna be bent into an open "C" shape
to begin with. Reason for using is cheapness as I have plenty of the stuff
but no rope. Can easily anchor center and ends so there is no "touching"
of anchors to antenna. Fast reply tonite would be most welcome as I can't
hardly wait for sun-up to get this thing in the air.<grin>

Oh yeah; if you don't mind one more quick question. Given 20AWG
450ohm ladderlind feeding 14AWG solid,....What could I expect it to support
in the way of PEP? How much power could I crank thru it if I ever got a linear?

Again, big, BIG THX !!

According to the news reports I heard, he plead guilty to a
misdemeanor. Hey Cecil, you're in Texas, howz come you don't know?
He's your governor!

You are wrong. It was a misdemeanor. What is your source of
information that calls it an "infraction"?

Thank you Wayne. Unlike you or Dr. Laura, I do hold an advanced degree in the field where she claims expertese. Consequently, I find her partuicular brand of mouthy impostership and clinical incompetence exceedingly offensive. But, this being American and all, you're sure free to think what you like--and to like what you think :<)

What does this have to do with antennas? Absolutely nothing. Which is fine because I've been working with them all day and need a break (hi).

> 'Doc

Rohn 25 will not self-support at 50 feet--the only time this is done is when a Hazer system is raising or lowering the antennas on hopefully a very, very calm day. If a house bracket is used, it is no longer a self supporting tower, and Rohn has published guidelines for these installations as well.

Also, the base requirements differ for different style bases. For example, a foldover base requires a minimal base, but it can only be used on guyed towers regardless of the number of square yards of concrete used below ground. It is very risky to accept anedoctal advice from newsgroup participants, especially when the specifics for your tower aren't specified.

The Rohn engineering plans are a must, IMHO; since there are insurance and safety issues, as well as zoning regulations, that come into play as well.

Pete

> make far field measurements.

I'm sorry; I intended that to apply to the context of the conversation we were having about an antenna that was 180 wavelenghts above ground. If you want to make far-field measurements of an antenna over ground, you will have to be 2D^2/lambda away from the antenna, with D = the largest dimension of the antenna system, including its height above ground.

> The electrostatic field energy decays as the sixth power of the
> distance. The induction field decays as the fourth power of tne
> distance. The radiation field continues into the far field and decays
> with square of the distance.

I believe that those are approximations, not absolute values. The EM field, in the far field, consists of both an electric and magnetic field. The individual fields (E and H) do not decay as the inverse square, but as the inverse. In the near field, if one gets VERY close to the radiating source, the E and H fields are reactive, ie, they return power to the source. But when one considers this field, one is really very close to the antenna and is subject to this intense, reactive field from only a portion of the antenna. It would be very much an oversimplification to sate the the E and H fields decay as 1/4 and 1/6 D. The nature of these field also depends very much on the voltage and current present on the antenna at the point in question -- near the ends of a half-wave dipole, for example, the E field is stronger than the H field by quite a bit, and vice versa at the center.

> A good picture of near and far fields is shown by Arnold B. Bailey`s

> dstances between 0.1 and 10,000 wavelengths. It is clear that after 5 or
> 10 wavelengths, that your are in the far field.

It depends on what you are trying to measure. If you want to consider the interaction of the antenna and the earth, you may need to be much farther away than 10 wavelengths from the antenna. If you have an antenna 10 wavelengths high, you would need to be 200 wavelengths away to get far-field measurements that accuately reflect the antenna-over-ground pattern.

> A very large antenna might not behave like a point source.

No practical antenna behaves like a point source.

> So I can see that some adjustment may be needed in the application of this
near field
> / far field information.

The boundary between near and far field areas near an antenna is a boundary for the radiating portion of the antenna fields. In essence, in the radiating near field area, one is affected more by one portion of the antenna than others. Thus the field present at that point is not determined equally by all of the radiation from the different parts of the antennna. In the radiating near field, one can even have cases where the E or H field becomes smaller as one gets closer to the antenna. The boundary is also "fuzzy," meaning that in all cases, as one gets farther and farther from the antenna, one gets closer and closer to the far-field relationship between the different radiating portions of the antenna. At what point is that relationship "close enough?" That is the near-field/far-field boundary. That point is generally taken to be 2D^2/lambda, but that is very much application dependent. If one is trying to measure the very deep null that is off the back or side of some beams, one might have to be much farther away to have the deviation from true far-field conditions not affect the measurement, just as one example.

Hi Cecil--

Doesn't alter the fact that the product provides a great solution for a lot of people. I wished I knew how to convice Mike to present more realistic claims, but--failing that--I wouldn't let it stop me from building or buying one. Indeed, I've used his, built my own, and feel pretty confident they all work just about the way physics and mother nature dictate they should. I do see your point, however. If dishonest people aren't allowed to overstate their case, honest people shouldn't be allowed, either.

His website seems a bit confusing. He has a graph that shows that the Hexbeam would have either a 4 or 6 dBd gain, under what he terms "line of sight" and "reflected path" conditions. I presume that the means free space and over ground conditions, with the reflected path considering ground gain. However, the FS numbers look about right -- around 4 dBd, but the reflected path numbers look a bit low. I would expect to see about 4 dB of ground gain. A dipole at a reasonable height above ground usually offers about 4 dBd gain.

This does not correspond to the claim that the antenna could show 10 dB of improvement over a dipole at the same height. An antenna that has 4 dBd free space gain could not do this under any circumstances I can think of. This may be based on some customer testimonials, but I don't see how it corresponds with the factual data on the Web page.

> The HEXBEAM is a good antenna that can stand on its own merits. Why must

> I'd like any input at all on what would be a good antenna to use and what
kind of pricing I can expect.

For the most part, for horizontally polarized (ie, horizontal dipole)
antennas, one must get height to expect good DX performance. If you want an
antenna that can talk to the world on 20 meters, then a 15-foot high dipole
is going to be somewhat disappointing. I would work *okay* on 80 and 40
meters for contacts out to a few hundred miles, but not really be great for
DX on any band.

The vertical would probably outperform the low horizontal antenna. There
are a number of verticals to choose from, some requiring ground connections
as an integral part of the antenna, others operating without a ground
connection. The latter can eliminate some of the losses associated with
poor ground, but for any vertical, the low-angle performance (ie, DX) will
be determined by the ground characteristics many wavelengths away from the
antenna. Some who live in areas of poor ground (rocky, dry sandy, etc) say
that a vertical antenna is an omnidirectional antenna that radiates equally
poorly in all directions. :-) Still, I think it would probably outdo a
dipole at 15 feet.

What you could do, however, if you can put up a vertical, is put a small
mast on the chimney and use it to support an inverted vee. I don't know how
much real estate you have, but if you can cut it about 50 feet to 150 feet
long and feed it with ladder line, you can probably use it on all bands 80 M
and up with an antenna tuner. My home antenna is a 40 meter inverted vee,
mounted on a 20-foot mast strapped to my chimney. I just used it /QRP in the
ARRL Sweepstakes and actually managed to make a number of contact calling
CQ. :-)

The thing to remember about building an antenna is that you are not building
your very last antenna, you are building your next antenna. I like wire
because wire is cheap. :-)

See http://www.arrl.org/tis and go to the information packages on
antennas -- there are a lot of QST articles available for free download.

Hi Cecil,

We're talking about two different things.

You are talking about the immediate year, I am talking about
obligations made and gone unpaid over the stretch of years.

If years ago you suffered the government to cover your losses (see the
debacle we called the Savings and Loan bailout), and then this year
say you want your excess taxes back, then that is redistribution of
wealth such that your erase prior debts for yourself and leave them to
everyone else to pay.

The Bushes (Bushii?) were highly leveraged in this Savings and Loan
fiasco. Uncle Sugar covered their losses, and now the Bushes want
their debt removed from the books (it was already paid by us suckers,
so why can't they have their excess taxes back?).

What's wrong with this if they paid the most and they should get back
the most? They got the greater return by pushing us into debt, and
now they want out of the payback. They made money in the first place
(using our funds AND taking the tax dodge for the loss) and now they
don't want to pay down the principle. That is redistribution of
wealth.

The people you should be pointing your finger at are those who defaulted on their loans from the S&L's because they paid too much for the property they bought. The money went to the folks who sold property at over-inflated prices. The government simply covered the deposits that our grandmothers had in their savings accounts so they wouldn't be out on the street. How you can blame that on George Bush is beyond comprehension.

In his last paragraph, Peter has touched on the most important part of all, insurance and safety. Years ago, someone might get away with a tower falling on a neighbor's property with little lasting ill effect. Now, however, as they say, in today's litigious society, I sure would want to be able to say: "It was installed to the manufacturer's specifications plus a 50% safety factor." if something untoward happened. And, it seems like the weather is getting wilder. We had a couple dozen power poles snapped in the middle in a thunderstorm yesterday, and that used to never happen. When I was a kid, back when dirt was new, I put up a tower with minimal guying, and sure enough, it blew down. Put a couple of holes in the roof, and broke most of the elements on one side of the tribander, and bent one of the tower sections. I made it a point that would never happen again. So I have a whole file of Rohn, Andrew, and Hy-Gain commercial tower specs. It sure makes the cement companies happy when I install a new tower now.

Ed Hare, W1RFI wrote:
"The individual fields (E and H) do not decay as the inverse square, but as the inverse."

So, why is it called "The Inverse Square Law"?

We are talking power per square meter here. Field strength is customarily quoted in volts per meter. This voltage is squared and divided by the 377 ohms of free space to obtain the power in a square meter of the wavefront.

The volts per meter in the far field decay linearly with distance from the sender. If you have a volt per meter at one mile from the transmitter at 1 MHz, you will have 0.5 volts per meter at two miles, less some additional loss from imperfect soil, etc.

With the power, the decay is 6db or divided by four every time you double the distance as we did in the second mile above.

The volts decay linearly with distance from the transmitter in the far field, but the power declines by the square of the distance from the sender. Hence, "The Inverse Square Law".

Ed is right, E and H don`t each decline by the square of the distance. But, the power in a square meter of the wavefront sure does.

Ed Hare, W1RFI wrote:
"It would be very much of an oversimplification to state the E and H fields decay as 1/4 and 1/6 D."

And it would be wrong. The above needs restatement to more nearly agree with my posting. I`ll try. The electrostatic field due to the high voltage points of the antenna decays in power as the sixth power of the distance from the radiator.

The induction field decays as the fourth power of the distance.

The radiation field near the radiator does not return, but continues its exodus to generate the far field. It decays as the square of the distance from the radiator.

Best regards, Richard Harrison, KB5WZI

Funny, you don't exhibit any such reticense to pontificate and deliver monologues. Perhaps you could try modifying the design to include things other than fractal antennas as well, to include lawsuits, firings, perceived abuse, and semitism to name just a few.

This is a discussion group about antennas. To discuss, according to Websters, is to "investigate by reasoning or argument". Investigation is precisely what draws many of us to this discussion. If you do not wish to participate in the discussions of fractal antennas, then why do post to a discussion group?

> antenna and its image.

The mutual coupling between the antenna and its image does indeed change as the distance between them varies. However, the "attenuation" between the antenna and its ground reflection does not affect the pattern -- at the infinite distance that NEC uses for far field calculations, the attenuation between the direct signal and the reflected signal is the same for both signals, so they will add or subtract to form a pattern.

> What this suggests to me is that the modeling program, at least for pattern

> impedance and fed with the same power, regardless of the separation between the
> "two" antennas. "Near" or "far" seem to have no bearing on the results.

> Seems to me that the model is wrong unless the antenna is "near" ground.

The model is not wrong. The effect of a reflection off of perfect ground is exactly the same as the effect of feeding another antenna, located 2H below the first antenna in free space, where H is the height of the antenna over perfect ground. In the far field, the patterns should be exactly as you describe, with exactly the 3 dB difference you describe. The far-field pattern is beign calculated at infinite distance, and the ground plane is infinite, so the antenna is always "near" ground as far as the far-field pattern is concerned.

>have never seen such an animal. Any ideas?

The problem is that you need a *lot* of isolation between the two radios on a duplexer in order to avoid leakage from the one transmitter to wipe out the sensitivity of the other receiver, since you want to be able to use both simultaneously.

In the case of multi-band duplexer, where one port is 146 MHz and the other 445 for example, the wide frequency separation allows good isolation just using ordinary filter components: capacitors and inductors. These can also be broadly enough tuned to cover all of both bands without adjustment.

But for the same sort of isolation between two frequencies in the same band, you need much narrower filters, typically cavity filters of some sort. Ask someone who operates a VHF repeater to show you the filters needed to operate a receiver and transmitter simultaneously 600 kHz apart at 146 MHz. There are typically several cavities in both the transmit and receive paths. These work, but they are big and expensive, and they need to be tuned to the specific transmit and receive frequencies in use. This could work if your voice and packet radios both operate on a single frequency each.

Dave

What's wrong, indeed. It simply is NOT TRUE. I assume that Mike knows it is not true, yet he passes it along anyway. IMO, that's snake oil marketing. "I didn't say it, they said it." Give us a break, Floyd. If someone says they can catch a .357m bullet in their teeth, are you going to pass that on as the truth? Mike should drop the "super-gain" stuff and admit that the highest possible gain of a two element beam over a dipole at the same height is about 5dB. IMO, he is simply trying to make a buck at the expense of ignorant hams. The Hexbeam is an excellent antenna that can stand on its own merits. Why must snake oil marketing techniques be employed?

I see posts from quite a number of engineers and scientists and other interested parties on this newsgroup and on others which certainly don't seem abusive to me, and which reflect accessibility. Perhaps, if you look at such exchanges (assuming you can find some you feel similarly about), you can determine for yourself what in them makes them that way. Then perhaps you can emulate that behavior. I don't mean that you have to agree with them technically, only that you use (one or more of) the styles as a prototype for expressing your own thoughts. -- Indeed, there are people who post here whose posts I really look forward to, because I almost always learn something from them. Frankly, yours have not been in that category for me, and the feedback I read from others tells me they aren't for a lot of others, too. If your postings are frequent, but not eagerly awaited, what response do you expect to them? I'm personally not very surprised by the responses I see.

I can tell you that it's a real turn-off to me to be told that details are available a certain place, only to find that indeed they are not there. It makes me very unlikely to bother to look when told of some other place they might be: like the boy who cried, "Wolf!" Or, "Fool me once, shame on you; fool me twice, shame on me."

It's clear to me that there are a few folk who post here who do not want to have productive exchanges with me; those are people I simply ignore. It's better for me, and it's better for them. Perhaps you could make that technique work for you as well.

It's your call, David. The physics are: Get the tallest antenna possible,
with the highest-Q center-mount coil possible, and the largest top hat
possible for your boundary conditions. I have seen screwdrivers mounted
on an Accord. Incidentally, that's the entire reason that I drive a full-
sized GMC pickup and I always score near the top in the 75m mobile shootouts.

Yep, that just means the 75m Hamstick is a lousy receiving antenna. :-)

I'll reiterate something Dave M. replied: duplexers are for all practical purposes fixed-tuned, and necessarily large to get very high Q.

However, you mention manual switching, so I assume that you really DON'T need to use both at the same time. If that's the case, perhaps there's some hope. One possibility is an automatic switch...perhaps just controlled by the power switch on one rig. Turn off the rig, and the antenna feed switches to the other rig. There are relays which have decent isolation at 150MHz, and you might even arrange to switch the "off" rig into a 50-ohm load, just to keep it happy in case it was turned on to transmit. I assume that you can figure out how to implement this idea.

You might also want to be able to monitor both radios at once, so long as neither was transmitting. If that's the case, there's maybe something that could be done with a PIN-diode-switched preamp that can feed two outputs for receive...but that all gets more complicated (and seems pretty disruptive for packet communications!). Let us know just what you have in mind operationally.

Hope this thought helps...

Cheers,
Tom

> of ground reflection upon both the pattern and the mutual impedance between the
> antenna and its image.

The mutual coupling is dominated by fields which decay much faster
than the radiation fields. The mutual impedance between an antenna 180
wl above ground and it's image is almost certainly negligible. The
effect of the 'image' antenna on the far field radiation pattern is
profound. As the distance approaches infinity, the difference in
field strength between the direct, and reflected (image) field becomes
negligible. The phase difference between the direct and reflected
field will change rapidly with elevation angle. Near the horizon, the
relative phase shift will rotate 360 degrees for every 0.16 degree
change in elevation angle.

> On the other hand, we have Ed's Eznec plot that clearly shows a pattern with
> myriad nulls that can only be due to equal, or nearly equal, amplitude and
> oppositely phased interference "signals."

I don't know which ground model Ed used but for low elevation angles
at UHF frequencies it doesn't matter much since the reflection
coefficient will be very close to -1 in the theoretical case of a
perfectly flat ground. As the elevation angle increases, partial
absorption of the reflected wave will result in shallower nulls and
slightly less peaking but the overall pattern will remain similar.
Real world conditions are often very close to the the theoretical
model for low elevation angles but surface roughness alters the
picture significantly for higher angles.

> regardless of the separation.

As the separation between the two radiators increases, so should the number of peaks and nulls. There should always be a null located along the perpendicular bisector (horizon) if the antennas are fed out of phase.

> What this suggests to me is that the modeling program, at least for pattern
> calculation, treats the perfect ground as a perfect image antenna with the same
> impedance and fed with the same power, regardless of the separation between the
> "two" antennas. "Near" or "far" seem to have no bearing on the results.

That's precisely what the 'perfect' ground model does. The 'real' ground model computes the complex reflection coefficient based on the angle of reflection and the specified material parameters. For horizontally polarized antennas, the low angle pattern will substantially independent of the ground parameters but you should see some filling in of the high angle nulls when the 'real' ground model is used.

> Seems to me that the model is wrong unless the antenna is "near" ground.

NEC does a good job of predicting the far field pattern over a flat homogenous earth. I imagine that if the overal physical size represented by the problem gets too large that numerical precision errors will creep in but I don't think that's problem for the scenerio's being discussed on this thread. The real world is often more complex than the NEC model but when used appropriately, NEC does a good job of predicting the far field radiation pattern of antenna systems.

> And I confused or what?

We all are probably :-) Certainly the semantics of what constitutes near and far effects varies with industry. For example, a radar system designer considers the far field pattern to be what NEC predicts (including cross polarization effects). The point to point microwave system engineering point of view is often to consider the interference arising from ground reflection as a propagation effect instead of an antenna system property.

My internet connection has been out for a day. Several postings I`d written are obviated, Here is one which may still be relavent.

Ed Hare wrote:
"With FF = 2D^2 / lambda, you would have to be 68400 wavelengths away to be in the far field to make accurate far field measurements."

I wasn`t familiar with that formula, but found a similar formula in Lenkurt Electric literature for the divide suggested for far field / near field from a microwave reflector:
d = 10 a^2 / pi lambda
Since we know the value of pi this can be stated as: d = 3.18 a^2 / lambda.

If I pick a as 3 feet for my 3 GHz which was a little under 3 feet long, for grins, and plug it in the formula, (the lambda is 0.333 feet), I get about 86 feet. I think Ed`s 22,777 feet is excessive.

Best regards, Richard Harrison, KB5WZI

All this started when someone said that a 3GHz rhombic at 60 feet above earth would not have an 11 db gain as it would in free space. I had predicted it would.

If I hang a dish specified as having 30 db gain in place of my rhombic, for my purposes it has 30 db gain. The fact that at the path grazing point Fresnel zones may add or subtract from the path db accounting, most microwave people would consider as a path development and no reflection on the dish`s gain figure.

I think it`s rational to think what happens out on the path is a path condition, not an antenna condition.

Best regards, Richard Harrison, KB5WZI

You are displaying you lack of understanding of the S&L failures. Many
people who had savings and investments in the S&L's would have lost
their money of the country had not bailed them out.

I've no doubt of this, and to date absolutely no one has been brought
before the bar of justice (insofar as that Texas S&L that Bush senior
snuffed any investigation for - for which Jeb worked).

The folks that lent the money (Jeb and associates) and those that took
it (Jeb and associates' friends) walked away free. The rest of us
paid for those losses with the investigations scotched. A cozy deal
in any state.

Thanks Bart;
I will try the 1/4 wave at RX freq and see what happens. The duplexer manufacturer recommended the cable be a multiple of 1/4 wave so I will defer to their experience on that issue and make a trial with that as well. Unfortunately, the station is not too well metered so it is not possible to see limiter or RSSI indications. The duplexers are Vari-Notch type and are generally good performers. Unfortunately as you noted, all these things tend to interact and we are troubleshooting "in field". Likely I will recommend the whole mess get looked at in the lab to better understand the problem. So far we are having problems even into a good dummy load, the antenna problems and site noise are another issue altogether!

That's a crime, if true. Since it wasn't prosecuted, there's at least
some indication that it might not be true.

I didn't vote for the one we've got out here, either. He still claims
to be my governor though. Better watch what I say.

Obviously, I didn't think long enough about this. The issue that was clogging
up my brain was the null that occurs "overhead" when the height above ground is
some multiple of 1/2 wavelength. The depth of the null is most certainly
dependent upon the ground characteristics, but not the number of wavelengths
above ground. To expand further upon my though process and where I went wrong
will just clog up everyone else's brains, so I will just stand corrected and
slink off.

Wes

Message-ID: <tv0h0tcnj8ad14c4j9rdd9hmakfqbidmc9@4ax.com>
Source record: 176944

Yes, I know a duplexer would not work. I was just giving that as an example of the functionality I was looking for. I really do want to be able to use both transceivers at essentially (but not necessarily exactly) the same time. I don't have a speaker on the packet radio, and I want it to be listening to the DX packet cluster frequency all the time. At the same time, I want to be able to pick up the mike on the VHF voice radio and transmit if someone is calling me. You have given me food for thought. Perhaps some kind of RF sensing switch on each radio mated to an antenna relay would do the job. The trick would be to keep the packet radio from over-riding the voice radio when I am talking on it. And not letting either radio see an open circuit at any time. Sounds like a good project for this winter. Or maybe I'll just take down the 6-meter beam on the tower and install a 2-meter beam in its place. What the heck. :-)

>The Hexbeam is an excellent antenna that can stand on its own merits. Why must snake oil marketing techniques be employed?<

My mantra, exactly, and it does sound like Mike is trimming things up a bit. The inaccurate performance of the average radio's S-meter and the anecdotal reports that result are partially responsible. Mike seems to be more careful now about identifying what is anecdotal and what is not.

David,

It really depends on what you want. The hard, fast rule is that you can have Pretty, or you can have Performance. The big, ugly antennas DO work better. Personally, I don't think a screwdriver would look bad on a Honda. And, of course, if you are willing to sacrifice signal for looks, then go for something "skinny". True, a hamstick will work, but how WELL? Comparing the difference between a hamstick, a Texas Bug-catcher, and a screwdriver is like the difference in a "real" antenna and a dummy load! (my opinion, but based on real tests) If you do some field tests, and you are as serious about HF mobile as I am, the dif-ference will make you sick! I know some people won't agree, but I can prove why the hamstick is not a good choice, and I'll only allude to it briefly. Have you ever wondered why a hamstick needs no impedance match at the feedpoint? Think about it.

Hope this helps

Doc,

This thread brings up a question for me. My 25G is 60', non-guyed, 5 feet in the ground, concrete, corner braced at 2 points to the house. It sits in a "L" shaped part of the house and braced on 2 sides. At 50', before I extended it, it stood thru Hurricane Hugo in '89. Do I have safety issues here? (Winds in that Hurricane were 96+ gusts).

TNX,

Jerry

You hold your self up as a target by making statements in this newsgroup and
then refusing to discuss them here any further. If you don't want to
discuss a topic here then don't bring it up as a subject for discussion.

>
> No sir; I see no problem whatsoever making relevant info available on this
> forum, and guiding to another link to assure that objective and relevant
> discussions may continue.

It ceases to be relevant info if you are unwilling to follow up on topics you bring up. On your reflector it is relevant because you discuss the topic there. Here it is irrelevant because you refuse to discuss the topic.
>
> Thus although I am aware of your opinion and respect it, I cannot take your

untenable adjective
not able to be supported or defended against criticism, or no longer able to continue

Are you saying you find that you have to make postings here that you refuse to back up. That you have tried and found that you were unable to continue not making them? That would be a compulsive disorder and should be checked out.
I highly doubt that you received criticism for not posting things you had no intentions of clarifying, elaborating on or discussing.
>
> This concludes my discussion on my availability on the internet.

The idea isn't that you are unavailable on the internet for open discussion of the fractal topic. The point is that you aren't available here where you keep bringing the subject up and then dropping it like a hot rock and then getting po'd when others comment on it or have incorrect assumptions.

A customer is talking to two produce salesmen at a farmers market and one says, "My carrots are better than his." The customer then asks, "What makes yours better?" Do you think the customer is going to go along with, "I'll only discuss that at my store"? Heck no. The customer is going to walk over to the other salesman who is willing to openly discuss the merits of his produce. Some may later check out the guy at the store and ask him there why he thinks his are better and may find out that he was in fact correct. Most, though, won't bother and will only deal with the other salesman in the future labeling the other man as a nut. Especially if every week he is there claiming to have improved the rutabegga or cumquat but refusing to give any details to support his claims. Add to that a little weasel faced guy on the back of the truck yelling at customers that this guy is a professional farmer and they are only customers and wouldn't know a good rhubarb if they saw it because they don't have credentials and then started cursing and muttering to himself.....
Just some "food" for thought. I know, bad pun but I like it.

I can believe that. With a 40' tower firmly attached to the house at the
30' mark, there would be very little leverage applied against the tower
base.

First of all, thanks for all of the replies (both public and private).

Ok, let's assume for a minute that I've been convinced that a screwdriver would be a better. Which one is the "best" (in your opinion) and would I be able to mount it to the ball hitch on my Accord? How long are those things anyway? I'd be primarily operating on 10, 15 and 20 and occasionally on 40 and 2 mtrs.

Thanks again,
David

1867. Re: Rhombic antenna for 10m

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-07 00:00:00 UTC
From: richardharrison@webtv.net
Message-ID: <4364-3A08E835-75@storefull-113.iap.bryant.webtv.net>
Source record: 176960

My contention is that the gain and directivity of my 3 GHz rhombic at 60 feet can be considered as an antenna in free space as microwave antennas normally are. At that elevation over smooth ground, the horizon is about 11 miles away. The "near field" extends only a small percentage of that distance.

I can measure the gain and directivity outside the near field and inside the path grazing distance. I will be susceptible to the ground reflection at my measurement location, but can screen it out. This is practical because I don`t have to move around my rhombic to measure, I can rotate the tiny rhombic. Or, I may choose some other technique to get rid of the reflected ray.

But, measurement wasn`t my initial goal. I already knew what to expect from the rhombic if it were reasonably clear of the ground. That was specified by the designer. I advised the questioner that were he to build the 10-meter rhombic, the 11 db gain figure wouldn`t be accurate because of the influence of the ground. The same would be true of a yagi or most other antennas.

Another questioner facetiously asked how he could fit a rhombic in a small space, and I responded he might scale it down by a factor of 100 and operate it at 3 GHz. But by not reducing the height, he should get the advertized 11 db gain.

At so many wavelengths above ground, the current and impedance into the rhombic will be very nearly the same as if the antenna were at any greater altitude, even way out in space.

What happens between a direct ray and a reflected ray at a point 11 miles away has nothing to do with the antenna`s characteristics, but with the characteristics of the path at the reflection point.

What signal a receiver gets from the combined contributions of the direct and reflected signals depends on the difference in distances each has traveled and conditions at the reflection point where the signal grazes the earth.

There are various opinions on the extent of the near field. There is no hard and fast definition because it ends where you decide it is no longer a problem to you.

Best regards, Richard Harrison, KB5WZI

Hi, Richard:

You forgot to blame the Bushes For TEFRA 1986, which, in one fell swoop, dropped the bottom out of the RE market and put Gramma's S&L (the one with no deposit insurance) in sole possession of acres of unsaleable RE. As I recall, same thing happened to the J's. One thing about foreigners owning the Empire State Building: when things go west, they can't pack up and take it home with them.

Hi Harry--

On the contrary: I am unwilling to answer fractal antenna questions HERE by design. However, as I have stated AT LEAST 12 times in the last year, I am happy to answer questions on the fractal antenna reflector:

fractalantenna-subscribe@egroups.com.
Thus I AM accessible on the web.

The extraordinary abuse and hate filled atmosphere create here by a few individuals does not make it conducive to discuss anything creative or innovative.

Harry, perhaps sincerely, you have a better suggestion which:

1) makes a scientist accessible;
2) prevents this abuse?

Cordially,

NC

>

The boundary between the radiating near-field and radiating far-field
is that point where the *radial* component of the E and H fields becomes
neglible. The 2D^2/lambda criterion specifies that point to be where
the phase difference between waves arriving from opposite sides of the
D-sized antenna aperture is 90 degrees. The fact that a radial field
component exists that far from the antenna is due to simple vector
addition of the transverse fields from point sources separated by
the distance D, not any energy storage mechanism. (That energy storage
region defines the reactive near-field).

1875. HF mobile (small car)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-07 00:00:00 UTC
From: David <k4zzrNONSPAM@gate.net>
Message-ID: <8u96t0$1nrm$1@news.gate.net>
Source record: 176998

Hello folks....

Last time I operated an HF rig mobile was back in the late '70's with an FT-101e sitting in the backseat of my Monte Carlo using a 20mtr Hustler on the bumper. I was very popular with the County Hunters back then as I drove through the hills of eastern Kentucky.

Now, I have a fairly small vehicle (Honda Accord coupe) but I'm bound and determined to put an HF rig in it (probably the Icom 706mk2g). I spend several hours a day driving around and would love to have a rig to listen to. I've been looking at all the choices for HF antennas and can't get a grip on what will work the best for me. Obviously the big screwdriver ones will perform well, but can you picture one of these on my Accord? I can't. What do you recommend? An antenna that will work *and* look ok on my car? And, if it matters, I'm willing to spend the big bucks for what will do the job.

Thanks for your advice,
David, K4ZZR

p.s. Just fyi, I've got a 1 1/4" ball hitch on the back of the car if that will help.

> the duplexers. Indeed the repeater manufacturer has provided a Z-Matcher
> in an attempt to fix the problem, and their rep has cut the cable to an
> arbitrary length that worked (for a time).

Has the Zmatcher been adjusted for minimum reflected power back into the transmitter? If so, the cable length shouldn't matter as long as the transmitter see's the 50 ohm load it was designed for at the transmitter frequency.

> The symptom is desense of the
> receiver due to TX noise. Cabling and shielding and other aspects of the
> repeaters are fine.

Severe mismatch of the transmitter output (at the Tx frequency) can result in increased intermodulation distortion but is not likely to significantly increase the wideband (or spot) noise at the receive frequency. Just to be sure, add approximately a quarter wavelength (at Rx frequency) of transmission line between the transmitter and Zmatcher. This should have no effect at the transmitter frequency where the load impedance is 50 ohms. The impedance seen by the transmitter at the receive frequency corresponds to a nearly perfect mismatch and will therefore be almost purely reactive at an arbitrary phase angle. Adding a quarter wavelength of transmission line will invert the reactance (half turn around the Smith chart) and can significantly alter the noise developed at the receive frequency by the transmitter.

> Normally I would spec an isolator panel in such a rare situation, but it
> appears that these are a rare commodity in this frequency range, very
> expensive and of questionable performance.

Does your duplexer have a notch filter on the transmit side tuned to the receive frequency? If so, it may need more careful tuning, especially after the feedline change suggested above. If not, you probably should add one.

> TX-RX's troubleshooting guide suggests that "adverse cable length" is a
> possible contributor to the problem.

The idea of course is to maximize the coupling from the transmitter to the antenna at the transmit frequency while minimizing the coupling between the transmitter and receiver, at both the transmit and receive

frequency. Transmission line lengths can have a dramatic effect depending on the design of the transmitter and duplexer.

> I have been given conflicting advice by sources who say "use an odd
> multiple of 1/4 wavelength" or "use an odd multiple of 1/2
> wavelength".

Unfortunately, the uncertainties in the duplexer characteristics make it very difficult to know in advance what the optimum cable length should be. Make up a couple of high quality patch cables and carefully experiment. There is a handfull of variables involved and it's pretty easy to get confused. I suggest you draw a schematic of the system and keep records of the receive limiter current (or RSSI) with transmitter on and off, for the various experimental configurations.

If you don't have a notch cavity for the transmitter, you can try a shorted half wave shunt stub tuned to the receive frequency, located between the Zmatcher and duplexer. The optimum location for the stub is at a place which is high impedance at the receive frequency. The correct location depends on duplexer design but would typically be 1/4 wavelength from the duplexer (I think).

1877. Re: hexbeam?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-07 00:00:00 UTC
From: Floyd Sense <sentek@sprintmail.com>
Message-ID: <8nVN5.203$qr.10182@newsread2.prod.itd.earthlink.net>
Source record: 177000

If one did not visit the www.hexbeam.com website and read it himself, one might believe that your statements have some basis in fact. I just left the site and extracted these two quotes from the pages of the Performance, and Supergain sections:

"Present HEX-BEAM users report an average signal improvement of approximately 10dB (2½ S-units) when compared to a dipole at similar height and a F/B ratio of approximately 10-30 dB. "

"In summary, you should expect to experience overall real gains with the HEX-BEAM in the range of 4 dBd (free-space and line-of-sight) to 10 dBd (reflected path) depending upon the installation and propagation conditions. "

Mike has refined the information on gain and front/back ratio several times over the past months, in an attempt to reflect what Hexbeam users are telling him and what he has observed in his testing with the antenna. Anyone who has done extensive antenna experimentation knows that you'll often observe results that can't be explained by what you know about antenna design and modeling. I have neither the inclination nor the resources to compare the forward gain of my antenna with a reference dipole. However, I've looked at the front/back ratio of the Hexbeam dozens of times, using a calibrated attenuator in the feedline to get accurate front/back numbers. With the exception of 20 meters, I see the ratio's that Mike talks about. Even though my f/b on 20 measures less than the 10 db 90% of the time, there are instances when I see far more than that. For example, I've seen a 35 db f/b on VK0MM's CW signals several times. I can't explain why this is true, but it is.

If Mike claims that some users have reported a 10 dB gain compared to a dipole, I take that to mean that users have told him they have seen that gain figure in relation to dipoles installed at their location. What's wrong with passing that information along? A reasonable person would read it and conclude that there is indeed some gain to be had with the Hexbeam, and it's not an insignificant amount. If your first inclination is to run to your PC and prove that it's simply impossible based on your models, then I feel sorry for you and suggest you might want to find another hobby.

As I stated before, I've talked with Mike Traffie on the telephone several times and, among other things, we discussed his performance claims and how they were stated. He was very concerned that he not appear to be making claims that might be interpretted as being unfounded. To demean him the way you have in this forum is simply wrong and uncalled for. Frankly, many of us who frequent this newsgroup are growing mighty weary of the personal attacks and negativism that you and a few others seem to thrive on.

I suggest you pick up the telephone and call Mr. Traffie and discuss your beef directly with him rather than venting here.

Message-ID: <rWVN5.174437$g6.78218789@news2.rdc2.tx.home.com>
Source record: 177004
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment

Do you remember the Antenna Specialist PDL-2 and Moonraker IV beams?

Well they have been discontinued! BUT, Antenna Specialist has approx
200 each of these left! They are also selling DIRECT!

PDL-2 = $85.88
Moonraker IV = $169.00

Shipping is $20.00 and they will charge you your local tax.

These antennas were designed for the 11 meter band which makes them
modifiable for the 10 meter band.

For the Moonraker IV, you would shorten each of the elements by cutting
the bottoms off and re-inserting them; shortening the fiberglass sections
and wire loop; re-spacing the elements on the boom; re-tuning the gamma
match section.

I DO NOT KNOW THE MEASUREMENTS! (Wish I did) I'm hoping that Roy
can (has?) model this antenna and will publish the info!

The PDL-2 modifications should be similar.

This is a GREAT opportunity to jump on well built and designed antennas
that are inexpensive and easy to turn!

Antennas Specialist says, "When they are gone...they are gone!"

Dino

If you are unwilling to answer questions HERE then don't bring the subject up HERE. Bringing up a subject you are unwilling to discuss is just dumb and literally invites abuse. Now you will probably give the reply, "How is it my fault that others choose to insult me? Here is another case of the innocent being blamed for others actions." That is BS and you know it, and if you don't you need to grow up and figure out how the world works before you interact with it any further or you are in for a lot of heart ache..

From 1996-1999 I did just that. I answered questions on this NG. But I see no reason to continue to allow ANYONE to hold me up as a target. It is beyond human decency, as readily seen in recent weeks.

No sir; I see no problem whatsoever making relevant info available on this forum, and guiding to another link to assure that objective and relevant discussions may continue.

Thus although I am aware of your opinion and respect it, I cannot take your suggestion, as I have historically found it untenable.

This concludes my discussion on my availability on the internet.

Cordially,

NC

I like Hamsticks. They are not as efficient as the monster-coil types
which I have used in the past, but they are not too long (7 feet),
unobtrusive, easy to tune, inexpensive and they get out ok for me. I
can work almost anything I hear and that's good enough.

I have two, VHF radios. One for voice and one for packet cluster. I would like them to be able to share the same 2-meter antenna without manual switching. A 2-meter/2-meter duplexer would be nice, but I have never seen such an animal. Any ideas?

I don't think you have seen one because a Duplexer will allow you to
use both radios at the same time which would be bad. Why wouldn't a
simple antenna switch work?

>Best regards, Richard Harrison, KB5WZI

This thread has progressed while I thought about this, but here goes anyway.

If I understand Richard's position correctly (always a dubious proposition on my part) he believes that increased height above ground causes increased path loss between the antenna and the ground underneath. This in turn reduces the effects of ground reflection upon both the pattern and the mutual impedance between the antenna and its image.

Figure 10 in Terman's book seems to bear this out. (Didn't think I had the book did you Richard?<g>)

On the other hand, we have Ed's Eznec plot that clearly shows a pattern with myriad nulls that can only be due to equal, or nearly equal, amplitude and oppositely phased interference "signals."

Intuitively, I agree with Richard. However, Eznec does not and it appears that one of them has to be wrong.

So I did a little modeling experiment as follows:

First I modeled a self-resonant dipole at 299.793 MHz (the Eznec example dipole tweaked in length for zero reactance) at some height above a perfect ground. Then I modeled a pair of the same dipoles spaced twice the height distance apart in free space. The second dipole was fed with the same current but 180 degrees phase difference. This in effect is the "image" antenna that is used in the perfect ground analogy as described in paragraph 4 of Terman's chapter on antennas and elsewhere. It should be noted that Terman qualifies by saying, "When the antenna is near the ground." What he considers "near" to be is unclear.

What I saw was that the patterns were identical except for the fact that the lower hemisphere was missing over the perfect ground and the amplitudes differed by three dB. The pattern peaks and nulls all occured at the same places regardless of the separation.

What this suggests to me is that the modeling program, at least for pattern calculation, treats the perfect ground as a perfect image antenna with the same impedance and fed with the same power, regardless of the separation between the "two" antennas. "Near" or "far" seem to have no bearing on the results.

Seems to me that the model is wrong unless the antenna is "near" ground.

And I confused or what?

In principle I agree 100% with Paul and Peter. On longer runs it is by far the best way to go. For only 15 feet though, the thought of having to retrench isn't that scary. Of course if the 15 feet is going to be covered with concrete or something then conduit is the way to go.

> voltage points of the antenna decays in power as the sixth power of the
> distance from the radiator.

The electrostatic field, which is expressed in volts/meter, from a point charge. drops off proportional to 1/R^2. The electrostatic field from a balanced pair of point charges of opposite polarity (electric dipole), falls off proportional to 1/R^3 as is also the case for a magnetic dipole. Balanced higher order distributions, e.g. quadrapoles, fall off faster yet.

The rhombic being discussed in this thread probably has a total of 10 wavelengths of wire making for a total of 20 'poles' in the antenna, plus another 20 in the primary image. Evaluating the field at any point in space is straightforward once the current distribution is known. Attempting to express the result in polar coordinates as a power series in R would likely be an exercise in futility. First of all, the solutions to the integrals involved (Ci(x) & Si(x) etc.) lack closed form expressions and secondly, there would be an overwhelming number of terms of various orders which would need sorting out....

>coax cable buryable?

PVC is not the best for burying. Polyethylene is better. See:

http://www.davisrf.com/ham1/coax.htm#buryflex

for more info. The usual disclaimer applies.

Also, if you live where there are burrowing critters like moles,
gophers, etc, put it in metal conduit. Plastic conduit is not a
sufficient barrier to them.

C'mon Cecil, we all know antenna advertisers go 'way over the edge when it comes to "gain" claims. Go check the fifty years of mindless hype in the Mosely and HyGain "specs", 10Db out of a short-boom tribander. As if. It's a shame they're compelled to pump out such transparent garbage but that's just the way they are. Traffie upped that "art" to a new low and hasn't done himself any favors in the process. Anybody who knows ferschtink about antennas ignores it all and moves on.
>
The hexbeam has a quite useful F/B ratio which 4dBd gain dipoles certainly do not have, my own philosophy being that lacking some 40 foot boom thingey or another with some actually noticeable forward gain I don't care about gain, I go for F/B ratio. "Ya can't work 'em if ya can't hear 'em", thus a hexbeam should be a big operating asset even with the same gain as a dipole installed at the same height over the same ground.

I know of NO state in which pleading gulity to DUI or DWI is a felony.
Repeats of a third offense are prosecutable as felonies in my state.

It's all a matter of public record, and I have no intention of doing
your research for you. Your mind (such as it is) is already made up and
such mundanities as facts couldn't begin to penetrate the granite that
is your skull. So stew in it.

1906. Atlanta area transmitter fox hunt

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-07 03:41:12 UTC
From: Penn McClatchey <pmmnospame@saf.com>
Message-ID: <3A0779E7.FCD15010@saf.com>
Source record: 176985

The Atlanta Radio Club is hosting a FOX HUNT this Saturday,
November 11th!! This hunt will be conducted at the Kennesaw
Mountain National Battlefield and the transmitter will be hidden
somewhere in the park. All are welcome. We will meet at 10:15 AM
at the visitors center at Kennesaw. For details see our website
at http://www.saf.com

The park is about 3 miles long and the hunt will be on foot.
A map of the park can be downloaded at http://www.nps.gov/kemo/

1907. TX to Duplexer cable, Adverse cable length? Advice?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-07 05:26:29 UTC
From: Joe Leikhim <jleikhim@nettally.com>
Message-ID: <3A079285.7E2F7557@nettally.com>
Source record: 176987

I have an application where some low-band (47 MHz) repeaters are being used with TX-RX duplexers (2 MHz T-R split). Apparently the solid state PA's in the repeaters are not at all happy with the inductive load of the duplexers. Indeed the repeater manufacturer has provided a Z-Matcher in an attempt to fix the problem, and their rep has cut the cable to an arbitrary length that worked (for a time). The symptom is desense of the receiver due to TX noise. Cabling and shielding and other aspects of the repeaters are fine.

Normally I would spec an isolator panel in such a rare situation, but it appears that these are a rare commodity in this frequency range, very expensive and of questionable performance.

TX-RX's troubleshooting guide suggests that "adverse cable length" is a possible contributor to the problem.

I have been given conflicting advice by sources who say "use an odd multiple of 1/4 wavelength" or "use an odd multiple of 1/2 wavelength".

Has anyone a definitive answer, hopefully with a reference for this problem?

Thanks!

Thx. for coming back Doc. I'm headed for Home Depot
to grab some rope. (Always thought it was goofy they were open 24/7
yet here I go <grin>).

No problems on the tuner for now, it's good for 300W and my
rig is rated 100W PEP. Good to hear the antenna will take whatever I
can throw at it. Wx. report is no rain until dusk on tues. nite. Will report
back, here's hoping !!

Mark,
How long have you been subscribed?? I have been watching with interest the parry and thrust of the Fractenna honcho and the rest of the thinking group, and its my opinion that Mr Cohen has been deliberately evasive in order to stir up interest in his airy fairy idea, maybe you should look back and read the postings, and then make you comment.

I disagree with W5YR on the resonance thing. If you can borrow a MFJ-259B somewhere, tuning should be easy. If you are already planning to have separate feeds (coax, I'm assuming), you can avoid interactions by juggling the feedpoint connection. You may find 15m and 10m interaction.

Also, Channel Master has a 30 foot telescoping TV mast that sells for $39.00 at my local Lowes. You could probably have it ordered if it is not in stock in your area. If you have a firm point to anchor against the side of your house, it should have no problem with a dipole. Its of hefty galvanized(i.e., better than "Radio Shack" quality). Guying may be called for it cannot be firmly anchored, and is a good idea anyway.

I wrote: "What happens between a direct ray and a reflected ray at a point 11 miles away has nothing to do with the antenna`s characterisitics, but with the characteristics of the path at the reflection point.

The reflection point may not be at 11 miles because it depends on the height of the antenna at the other end of the path in addition to the height of the small rhombic of interest.

The reflection point is only at half the path length where the antennas are at equal heights. The reflection point is unique. No other ground reflections reach the antennas at the ends of the path in the usual case. The angle of incidence is equal to the angle of reflection.

Best regards, Richard Harrison, KB5WZI

1915. EMAIL PROCESSORS WANTED

#1 - VERY BRIEF INTRODUCTION

Due to an enormous client list, I can only take serious applicants at this time. I am offering a full or part-time position in processing e-mail. You can work at home. I do require that you have a computer and are familiar with internet/e-mail functions. As to the salary it's totally up to you. You will be running your own business, the sky is the limit. What you will see represents a totally legal money making business that anyone can generate a significant residual income.

You will receive full instructions, and I will always be available to help you and answer your questions. This is a genuine home business. This is not a chain letter, money game, telecom scheme, or any of the multitudes of dubious "business" offers that come through your e-mail box. This business will generate a residual income of $2,000 to $6,000 every month with only part-time commitment (about 10 hours a week).

A full time commitment (about 30 hours a week) based on statistics gathered from associates world wide, will translate into an income of $10,000 or more per month!

To prove my confidence and sincerity in this opportunity, there is NO CHARGE to join us for the first month. You will receive all information to get started plus the first month's information package ($90 value). If by remote chance you are not satisfied with the program after the first month and want to discontinue, you may by all means do so and I will not contact you again.

But on the other hand, if you are satisfied with the program and wish to continue after the first month, that is when you have to pay $90 for the next month's information package. Since you DO NOT pay anything until after you are already earning an incredible residual income, you have absolutely nothing to lose.

IMPORTANT!

If the above opportunity interests you in the least, and you would like more specific information about our business please contact me at adenby@consultant.com and type in the SUBJECT LINE: "FORWARD PROJECT 21 INFO". Insert your full name, your correct e-mail address, and any specific questions you may have at this time in the body of the message.

We are successful only if YOU are successful, and therefore we will do everything in our power to ensure that your relationship with us is a profitable and successful one. I look forward to your response.

Sincerely,
Angela Denby

Hello Mike:

I agree with you about these antennas because I too had one in the early70's and all that has to be done to modify them is to cut about about 4" off of each stainless steel radial end in addition to shrinking the circumference of the reflector loop by about 1'.

However if one is to use the Moonraker 4 for 10 meter ham use, the vertical half of the antenna is wasted because it doesnt get used (unless contacting local 10 meter mobiles is considered). If one takes away the vertical use of this antenna, all one has left is a 4 element horizontal quagi which can be bought or homemade for alot less than $169. I agree that if one of these antennas were a freebee or a gift for someone that it would definately be worth the time installing, but not if one has to buy it new for $169.

The PDL II (AV-122) on the otherhand is definately worth buying for $89 (if this is the correct price) and converting it to10 meters because the fiberglass spreader arms and the orbital gamma matching sections alone are probably worth $30-$40. Not to mention the mounting hardware, the #14 bare copper wire, and the boom itself.

1918. Gain of 1/4 vertical over salt water?

Newsgroup: rec.radio.amateur.antenna

I am going to be putting up a 1/4 verticals for 20 and 40 meters next to
a salt water slough. How much gain could I expect to get on my receive
and transmitt over the salt water?
I've seen various articles about the adavantages but I never really seen
a definitive answer on this.

Thanks!

Jeff

I agree, after being on this reflector from 2 years, that I havent seen anything interesting from Fractenna and his friends.
I now think that they have little knowledgement about antennas matter, and they like only to disturb this reflector sewing hate and the worst things.
So from some time I HAVE USED MY MICROSOFT
EXPLORER TO FILTER ALL FRACTENNA AND FRIENDS MESSAGES.

PLEASE ALL OM ON THE REFLECTOR FILTER THESE MESSAGES AND STOP REPLY TO THE MR. FRACTENNA, RETURNING THIS REFLECTOR TO AN ANTENNAS DISCUSSION FORUM.

PLEASE UNDERSTAND THAT THIS KIND OF PEOPLE NEED BE LEFT ALONE, HOPING THEY TAKE THE MEDICAL CARE THEY NEED.
By the way, I am going to filter also all message with "hatred" in the subject - hi!

You can expect about 10 - 15 dB gain over inland verticals with average radial system and vertical pattern to reach down to horizon - very low angles.
See
http://pages.prodigy.net/k2kw/
by Team Vertical (and Force 12 bunch) about their experiences with verticals on the beach.
I just did some operating with simple verticals on the beach from Cape Hatteras during CQ WW phone on 10m and I am impressed!

Source record: 176880

Whenever you talk about gain, you have to include what the gain is relative to. If you're asking about how much gain you'll get relative to the same antenna over average ground, the answer depends on the elevation angle. At very low angles above the horizon, which are important for working DX, the gain will be considerable if the salt water extends for at least a few hundred feet beyond the antenna. A quick run with EZNEC on 40 meters, comparing salt water with average ground on 40 meters, shows about 10 dB at 5 degrees elevation angle, about 6 dB at 10 degrees, and 5 dB at 20 degrees. These assume that you have a very good ground radial system. If you have only a few radials, you'll pick up a bit more at all angles because the ground system loss will be less for the same number of radials when the radial system is just over salt water.

You can easily see this for yourself, and make other comparisons, with the free EZNEC demo program available from http://eznec.com.

This is a very intersetin thread.
I have breen off of the low bands for a long time, and recently got a
IC-735. I'm using a G5RV in a vee configuration, and even pinched in a
horizontal vee facing East. I use it mostly on ten and forty, and get
excellent rteports. Low noise is a plus. I have a limited space, and
the rear of my residential property has high voltage lines, but it
still seems to work great. I don't know what I can do to improve on
it, but I'm listening, , , :-}~

1925. parasitic vertical array

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-08 00:00:00 UTC
From: Lennart Grahn <lennart.grahn@iname.com>
Message-ID: <8ucf7c$9jd$1@nnrp1.deja.com>
Source record: 176882

Hello antenna people

I read some old postings in rec.radio.amateur.antenna. I search on a favourite subject: parasitic vertical array, and I see a thread that I started some 18 months ago.

The thread was:
"Anyone else experimenting with several verticals, one is feed"

At this time I am ready with three elements, all in line, distance 0.25 lambda and just the centre is feed. The band I am using is 40 meters.

The results are great, really great I should say.

Directional beaming is made by shorting one element with a capacitor. The other one is slightly longer than the centre element.

Achieved FB is equal with my 4 el yagi for 20 meter up about 18 meters. Gain compared to a single GP is noticeable. Received signal difference on long distance, when compared with a single GP or a delta loop is between 1-3 S units.

The single GP has fever radials than the array, about 36 compared to 72 for the array, for each element.

Forward direction may be S7-S8, and backward S1. (Best case, recorded on a normal ham receiver.)

Measured impedance at bottom of center element is about 22-24 ohm. Impedance matching is done.

The system did for some reason not produce any good FB when I had just two elements. The real kick was when I decide to work with three elements. With three elements it was possible to null away the back signal much, much better than with two elements.

It is very nice to be able to rapidly switch direction; to give me a indication of witch signals comes from northeast (UA9, JA, HL, VK, ZL ..), and which comes from southwest (Europe, and South America).

Now I can work them from my QTH, DX that I very seldom heard on 40 before.

I say, that vertical parasitic ground plane antennas, do work.

Best regards

SM2IXM

Compared to a well-designed Bugcatcher, a 75m Hamstick will lower
far-field QRM by 12dB. :-)

That depends, in part, in how good your GP is to start with.

The best you can do above a with perfect , infinite grounds is about 5.4 dBi(unless you raise your radials more than a bit).. That will peak at the horizon. In practice you will get within a dB or two of that with the proximity to sea water, and your launch angle will be approximately 10 degrees.

I would say, typically, you will experience a 3-5 dB gain compared typical grounds.

This is a self-contradictory, personal attack by Jim Pennino against me

Why do we tolerate this??

On what basis , Jim, do you, or anyone else who claims I have some mental debility, feel that you have the right or expertise to make such assertions?

Are you aware that I have stated many times--including just the other day--that if someone wants to arrange and pay for a shrink from Maclean Hospital to meet with me I've said 'no problem'? As long as you pay== and the report is made public?

Why is this tactic of personal attack now concentrated on this fantasy of mental illness??

Why this obsession with ME, even when I don't participate in discussions?

Greetings,

Well, it's up. LOTS of compromises made. For one underestimated
available length I had because didn't take into account the "extra" length
needed for angle/elevation changes. Coulda had an honest 264ft. (Sigh)
but didn't realize until too late. Also, this left my wire ends 30ft. up in one
case and 50+ ft. in the other-- so had to tye down with rope and no insulators
otherwise. Too high up to reach and do anything else.

On the positive side, It's up !! Finally. 450 ohm ladderline is very
well soldered and secured so wind will strain center block, not 450 ohm.
Height there is 56 ft. The whole thing is zig-zag and dog-legged but that
never stopped the random from working well on certain bands Considering
lengthy rope, reasonably secure with some slack on ladderline in case
adjustments are needed later. Ladderline never within 4 inches of other metal.
Antenna more than 4ft. minimum from old random, usually much more..

A hunk of a Dominoes Pizza box is my window feed point for now and
will replace with plexi/wood whatever once I'm more settled in. Gnd is to old
8ft. that's about 18ft. from where rig will be and will pound another one down
closer in the by and by. (Better hurry, ground's getting cold--<grin>)

Might get tuned up tonite, but more likely the weekend and will report
back with test reports. Kinda nervous over so much effort, here's hoping ! Thx.
for all everyones help.

73,

Andrew

I missed the initial post and it is no longer on my server, but if you are talking about conduit, the PVC stuff works just fine. If you install your own underground service the power company requires it around here.

As for using it with coax, I'd install at least two inch and seal the joints.
When you put the stuff together run a nylon line through it so you will have a way to pull the coax through.

Each time you pull a coax through, tie a rope, or nylon line to the front so that you pull a new line in which will allow pulling in the next run(s).

I'm currently using a 30 foot run of 5 inch plastic sewer pipe with a 45 set up to drain into the sand backfill. So...any water that does get into the line is drained, rather than running on into the basement. Also the inlet points down with drip loops in all of the cables.

One thing I do is throw in a few mothballs and then plug the pipe at the basement end with a small towel. The towel keeps the breeze down to a minimum and the mothballs keep the critters out.

With the new tower, I'll be using three inch PVC conduit as there will be 7 runs of LMR 400, two runs of RG-6, and three runs of 8 conductor cable.

There is a version of LMR 400, (LMR-400U, I think) that has a gel in the braid for direct burial. Wish they'd had this stuff before I installed all the cable on the old tower.

OK, what does it do without the coil? I hear folks screaming 1:1, 1:1, etc and just can't stand it if they can't get below 1:4 or 5. The difference between the 2 figures is so minute that there isn't a SSM that will read it. That's OK, if it floats yer boat (no flames intended), but I never spend extra time trying to get down to 1:1. If it happens to go that low, fine. But it really ain't worth the trouble.

Even with the matching coil, the ham stick is a sorry antenna compared to the "big-ugly" ones. Here's why: There are 3 resistances your RF has to overcome to "launch" into the ether; feedpoint, coil, and radiation resistance. Can't be much done about radiation resistance, but something CAN be done about the other two. Say....you have 10 ohms of feedpoint (impedance) R, 30 ohms of coil resistance, and 8 ohms of rediation resistance. Totals up to right at 50 ohms, right? Trouble is, the major part of the total resistance is up in that "tiny" loading coil. The rig doesn't care WHERE it gets the 50 ohms from, but the fact is, in a hamstick, the largest resistance is up in the loading coil where it becomes an obstacle. Your RF is (a good bit) is wasted as heat! Since 1:1 is not that much different from 1:5, the coil in a hamstick is STILL inefficient--even at 1:1. Even a dummy load is often 1:1! LOL!

A high Q HF mobile antenna will exhibit low impedance (around 18 ohms or so), therefore they won't work without increasing the impedance at the feedpoint to match the load to the transmitter. Of course, the higher you go (the above example is at 75 meters), the less critical matching becomes. Generally speaking, a hamstick won't require matching. They usually will match, for the above reasons given.

The whole thing is really a question of how serious you are about mobiling. If it works fine for you, then it is fine. But if you ever test a hamstick against most other HF antennas, you can readily see how inefficient they are.

I have built quite a few screwdrivers-- which is a really great antenna for the serious mobile operator. The current one is a 3" version which approximates the old #66 Texas Bugcatcher coil. It is a fantastic per-

former. I get really good signal reports from stations all over. IMHO,
I would not consider a hamstick for a mobile antenna.

Best 73

Jerry

Agreed, but the original question was about finding an unobtrusive
antenna... not the most efficient. Everyone agrees that big and ugly
is most efficient. No question about it. Everyone who has used a
Hamstick also knows that they do work well enough to get out and make
contacts. It's a compromise, no argument there.

I have had a big, ugly, high-Q, homebrew antenna which worked VERY
well, and I have also had Hamsticks. I prefer the Hamsticks, but I
would never take one to a shootout. I'd get laughed out of town, but
on my way out I'd be working stations all over the country. I'm
happy.

FS:CUSHCRAFT R7000 HF VERTICAL ANTENNA

Cushcraft 10, 12, 15, 17, 20, 30, 40 Meters HF antenna with
manual. Complete and in Good shape. Works great dx. This is a half wave
on
all above bands. 5 yrs old. Rated at 1500 watts. Has never had more than

100 watts run through it. Can roof mount etc. Has it's own radial system

built in with a small footprint. Already assembled, I broke it down into
3
sections for transport. Marked the joints with a felt marker for easy
setup.
This is a very GOOD antenna. I have too many overhead power lines to
safely
set up here at my home. Antenna is 24 ft. long.
Price is: $150.00 firm. Buyer must pick up in Escondido, Ca., North San
Diego
County. Sorry...I will not ship. Feel free to email any questions to me:

John Williams at ac6ts@n2.net or ac6ts@amsat.org

Thank you for reading.

1942. OT: Antenna matching transfomer for FM broadcast band

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-08 00:00:00 UTC
From: Carl-Lisa Van Camp <thevancamps@interwebco.com>
Message-ID: <tKnO5.85$D_2.38955@news-east.usenetserver.com>
Source record: 176899

Sorry for the OT post, but I bet someone here knows: I'm trying to find a 50ohm-to-75ohm RF transformer that covers the FM broadcast band (88-108MHz). Ideally it would be BNC connectors in and out.

Goal: hook a 75 ohm antenna to a 50 ohm spectrum analyzer input. Anybody know where I can buy one of these?

TIA,
Carl Van Camp
Chicago

1943. Re: OT: Antenna matching transfomer for FM broadcast band

Newsgroup: rec.radio.amateur.antenna

Source record: 176900

I'd just put a 27 ohm resistor in series with the spectrum analyzer
input if I needed a matched termination, but I'd be surprised if that
would make any noticeable difference compared to just connecting it
directly (except a 3.7 dB reduction in signal strength).

On or about 08 Nov 2000 23:45:00 GMT, fractenna@aol.com (Fractenna),
using the forum rec.radio.amateur.antenna did say:
:
:
:This is a self-contradictory, personal attack by Jim Pennino against me
:
:Why do we tolerate this??
:
:On what basis , Jim, do you, or anyone else who claims I have some mental
:debility, feel that you have the right or expertise to make such assertions?
:
:Are you aware that I have stated many times--including just the other day--that
:if someone wants to arrange and pay for a shrink from Maclean Hospital to meet
:with me I've said 'no problem'? As long as you pay== and the report is made
:public?
:
:Why is this tactic of personal attack now concentrated on this fantasy of
:mental illness??
:
:Why this obsession with ME, even when I don't participate in discussions?
:
:NC

Because, NC, you bring up subjects, and when asked questions about
your vague points, you go ballistic and refuse to answer their
questions, instead pointing to a lame duck website that does not
contain the answers to the questions asked.

Through all this, you maintain an attitude of aloofness, superiority,
and cockiness which is, apparently, unwarranted.

From what I can tell these "attacks" didn't start happening until you
started baiting the NG, then refusing to answer questions..

Are we starting to see a trend here?

Just my two cents. Your mileage may vary.

Paul,

You are exactly right about the vert portion. The reason I mentioned it is we set my Dad up with a Ten meter mobile. Besides his mobile, I noticed a lot of mobile stations with considerable better reception on the vert. This also helped in local FM modes. I never tried it DX on AM or FM though. It would be interesting.

It was a long time ago and I remember it was fun and challeging to mod this ant.

If you are feeding a spectrum analyzer, just connect it up. The mismatch will be insignificant if you are looking at the FM band.

You can always make a bigger coil for it. Thats what I did on one of
the sticks I have. "5 ft helical whip with a large coil halfway up, and
a 3 ft stinger". I'll take on any 8 ft bugcatcher or screwdriver with
it. I doubt you could see any difference. I've beat a few bugcatchers
that were not set up for maximum performance. Also a 75 meter hamstick
should be just as good at receiving as any other small vertical. The s/n
ratio should be about the same as a high q coil antenna. Now transmit
with the narrow helical windings, thats a different story. MK

Message-ID: <14588-3A0A3B13-59@storefull-107.iap.bryant.webtv.net>
Source record: 176907

I am looking for one of the following antenna tuners.
1. Dentron MT-3000a or 2000a
2. Heathkit 2060
3. Nye Viking
4. X Match
5. Harris
6. Ameritron ATR-30
7. Pal Star AT-4k
The tuner I am looking for must be able to withstand at least 2kw CW on 160 meters.
It must be able to tune balanced and unbalanced lines, and have a switch for selecting between the balanced or unbalanced antenna to be tuned.
I am not interested in any MFJ junk, or anything along those lines. I am not interested in any tuner that wont tune 160 meters. I am not interested in a tuner that has been hit by lightning or has signs of flashover inside the cabinet.
The tuner must be clean and in good working condition.
Thanks for your time and 73

They do exist, but probably not in the form that you are expecting. To do in-band duplex in the 2m band requires large tuned cavities. This is what we use to duplex a receiver and a transmitter to make a 2m repeater. This is the only common use in the ham bands. At commercial sites, they are occasionally used to duplex multiple transceivers onto a common antenna. Unfortunately, to buy these new, they are prohibitively expensive (for common use). For example, the 4 cavity duplexer on our club repeater cost over $1000!

David,
I know you mentioned the IC 706MK2G, but the Yaesu FT 100 and the ATAS 100
would be an excellent combination for you. The ATAS 100 covers 70 cm/ 40 mtrs
with a diplexer. It if fully auto tunable with the rig. the antenna is only 48
inches retracted and I believe 62 inches fully extended at 40 meters. I
managed 60 contacts in 1 1/2 hours out of the mobile 2 weekends ago during the
contest on all of the HF bands, and contacts on 6/2/70 cm. Despite all of the
bad things you hear on the FT 100 ther are as many or more people that are
extremely happy with the FT 100. Great Rig and with the ATAS 100 it is one
fantastic mobile rig.
73 and Good Luck

Source record: 176961

Circumstances make available a roller inductor listed previously. It is brand new, edgewound, silver plated, 24 uH, 20 Amps, 3 KW ++. Sells for $240 at Surplus Sales of Nebraska. Has a shaft at both ends. Double wiper so there are no "skips" causing the swr meter to spike while the inductor is being rotated. Has a geared potentiometer for a position indicator if you remote tune the coil. Has an end of rotation limit switch if you choose to remote control the coil. Price is $75 plus UPS, will not ship overseas.

Thanks for reading the posting.

73s,

Evan

I'll dig out my Rohn spec book but I'll bet that a 60' tower in 5' of
concrete (how many yards?), with house brackets at two points is rated
for very high winds.

I had a 40' 25G with NO concrete -- it was on a base staked into the
ground -- eave bracket at 30' and it was rated at a lot of MPH with the
10 sq ft of antennas I had on it.

I'll end this thread here. You're ignoring the facts entirely. As you can see in my quote which you included below, the gentleman said that "some users have reported a 10 dB gain.....". He did not say: "This antenna will give you a 10 dB gain compared to a dipole." Do you not see the difference ?? I know for a fact that his statement is absolutely true because I called many of the hams on his list of reference sales and they told me the same thing. I didn't take their claims literally, but understood that they saw "pretty good" gain in relation to their other antennas. If I were to follow your modeling derived rules, I would come to the conclusion that EVERYTIME I measured a two element beam compared to a dipole, I would see a 5 dB difference, assuming I accurately measured the difference. On a test range, you could undoubtedly measure the result you claim, but, in a real station, you'd be hard pressed to see that exact difference on even one single contact.

I don't know where you've been for the last 20 years, but marketing in America is based on the ignorance of the prospective customers. The difference between you and I is this: You read the claims, declare them to be impossible or untrue, and brand the seller a liar and snake-oil salesman. How in the hell do you ever buy anything these days? I read the claims, make an intelligent judgement as to the degree of truth after subtracting the marketing hype, and then buy or don't buy. I don't take the time to tell everyone else that the seller is a liar.

We are in agreement on the "super-gain" business.

I mentioned using PVC several posts back, but, that was in reference to the
gray electrical PVC conduit sold at Graybar and other electrical
distributors,
which is designed for protecting direct burial electrical cables. The PVC
reference I had made was to the conduit material, not the coaxial jacket..

THE most fundamental value within the mental health field is confidentiality. A rare naughty psychiatrist may cross the line and sleep with an especially needy (and delicious) client, but none would ever publically disclose anything concerning a "psych eval" without handfulls of court papers and drawn guns pointed at their heads! The offer exceeds absurdity. You can't buy what's not for sale.

There's a slight difference. Instead of being a man and claiming 10dB gain,
he blaims it on "users" when he knows those users don't know what they are talking
about. If a "user" reported being able to fly to the moon in a Piper Cub, would
he also publish that as the truth?

> ?? I know for a fact that his statement is absolutely true because I called

If their claims were not taken literally, why were they published literally?
It reminds me of the SGC ad where they claimed their mobile antenna system
would punch holes in the laws of physics.

> I were to
> follow your modeling derived rules, I would come to the conclusion that

5dB is approximate. But it is certainly not 5dB plus or minus 5dB.

I don't want you or ANY ONE ELSE to stop talking about fractal antennas. If you want to then go ahead! I WILL exhort you to be accurate and precise and not spread misinformation.

I will NOT accept harassing and libelous statements and personal attacks from anyone.

If your comments are motivated by business and NOT science, then I will continue to make this clear.

It seems to me if no problem is produced then no solution is necessary.

I don't mind or care what you say, as long as it is technically accurate (or attempts to be), relevant, not of a personal nature nor one targeted at a competing firm.

Doesn't this make sense?

Cordially,

NC

I had figured that if we are going to talk about antenna gain over ground, then real ground would be a better choice of modeling, especially after I had tossed out the figure of 4 dB for typical ground gain. I see why perfect ground was brought into the discussion when the discussion changed context a bit, but my example was not intended to be perfect ground.

Perhaps you have lost sight of the original premise -- that if you want to measure the pattern of an antenna over ground, you need to be in the far field and the calculation of the far-field distance needs to take into account the height above ground of the antenna for D in the far-field formula.

Mark,

Just a few comments. I agree with you that you can't beat a bugcatcher
or large dia. loading coil for best performance. There are, however,
<<some>> disadvantages, and that primarily comes from the fact that
coil antennas are fixed-tuned. Due their high Q, they are more easily
affected by their surroundings. So as you move along past power lines,
water tanks, cell towers, and other vehicles, it may become detuned--
at least until you get away from the object that was causing the condi-
tion. The other thing is the "jumper" or tap that one has to use to
change bands. Even though the turns below the tap are bypassed, these
turns still exhibit <<some>> loading. This can cause trouble. Usually
it is a minor thing, but, in my case, I have had a bugcatcher that would
not resonate on a certain band because of the "backlash" (for lack of a
better term) caused by those "shorted" turns. Nothing I could do.
So, there ARE times when a screwdriver just "might" beat a bugcatcher
due to the agility of the thing. In other words, where the bugcatcher
might be rendered temporarily useless by its environment, the screw-
driver could continue on virtually unabated with a touch of the switch,
placing it back in resonance since it can compensate for changes. After
all, you can't exactly jump out onto the trunk and retune at 65 per!
LOL! I've had this very thing happen lots of times; in QSO and a big
truck pulls alongside detuning my antenna. Just a touch on the switch
and I'm right back in business! Love "dem" screwdrivers! LOL!

BTW, I made a screwdriver that is roughly the same size as the old Texas
Bugcatcher #66 coil. It is 3" in dia, giving me roughly the same high
Q as the BC, and the convenience of the SD. Works great! You know,
BIG'n'Ugly! LOL!

Dennis Ferguson wrote:
Actually, I think your way doesn`t compute with respect to conservation of energy.

I agree that confining the energy that would fill a sphere to a hemisphere doubles the energy density due to the confinement. A 3db gain is achieved over isotropic radiation.

But, the energy from an antenna 180 wavelengths above ground is spread far and wide before it reaches the ground. There is nothing to focus the energy on the ground space directly under the antenna, and the energy certainly is not columnated as is laser light. The volts per meter and the watts per square meter are greatly reduced at ground level. The energy available to an image antenna is significantly reduced.

Remember that the image antenna should behave exactly as an actual antenna would in the virtual position were that perfect ground removed and replaced with a real parasitic antenna. Scratch the parasitic if the antenna is driven against ground.

Why is a Yagi reflector placed 0.1 to 0.3 wavelength behind the driven element? Would it receive the same excitation at a distance of 180 wavelengths? You know the answers.

In arrays where all the elements are driven, we can adjust the current ratios to suit ourselves. That isn`t true in parasitic arrays without adjusting spacing between the elements.

Radiation from the image of a dipole 180 wavelengths above earth doesn`t begin to equal the radiation from the elevated dipole. No violation of energy conservation rules are in volved. Only geometrical spreading is involved.

I`ll give you a microwave example.
You may have seen what used to be a common sight. It is called a periscope antenna. A rather large dish on the ground, stub tower, or top of the radio shack, would be aimed at a reflector at the top of the tower, most often at about 45 degrees, to direct signals horizontally along the microwave path. Very large dishes were often needed to focus the microwaves so that the first Fresnel zone of energy would all hit the reflector. Without the focus of energy on the reflector most of the energy would be wasted in useless directions. Spreading of the energy is great at great distances such as 180 wavelengths unless rather heroic measures are taken to prevent wide dispersion.

Best regards, Richard Harrison, KB5WZI

I think I see the reason for some of the differences of opinion here, Richard. I am thinking antennas that are primarily used for ionospheric propagation and you are thinking of antennas that are primarily used for line of sight. In that case, one does need to think of ground differently. In the case of the ionospheric propagation, one is mainly concerned with radiation towards the ionosphere. This radiation is determined, for any specific propagation angle, by the direct ray from the antenna and a ground reflection that takes place at a specific point. If one is determining the antenna pattern of such an HF antenna over ground, one must consider the effect of that ground to obtain a realistic estimate of the actual gain of the antenna. That gain can be used in various propagation prediction methods to estimate signal strength to a distant point. One cannot measure the actual gain at any elevation angle without including the ground reflection and one must be in the far field to do it. Under those circumstances, my caution that one must include the antenna height above ground to determine the far-field distance is correct. The point where the signal will be received is >> 2D^2/lambda, where D is the height of the antenna above ground or the distance between the antenna and the reflection point.

Your example for a microwave antenna is somewhat different, with the direct ray from the antenna that is useful generally being toward the horizon, and the reflection point being, as a first approximation for antennas of equal height, midway on the path. In this case, however, the point where the signal is being received is NOT >> 2D^2/lambda from the distance between the antenna and reflection point, so one cannot really make measurements in the far field at all, at least not the far field of the interaction between the antenna and ground, so thinking in terms of the fresnel reflections makes a lot more engineering sense.

In either case, however, the gain of the antenna between the source antenna and the receptor antenna is generally going to be different than free space conditions. Using EZNEC, I modeled a 100 MHz half-wave dipole in free space and placed a half-wave dipole 1000 meters away, with a 72 ohm load resistor in the center. I used EZNEC to calculate the power that would be induced in the load resistor when 1000 watts was applied to the first dipole in free space, with both dipoles 1 wavelength above ground, with both dipoles 100

wavelengths above ground and with both dipoles 100.5 wavelenghts above ground. I found the following, expressed in dBkW:

free space 1 lambda 100 lambda 100.5 lambda
-77.7 dB -115.5 -76.99 -95.78

The last two are not errors. Running with smaller steps:

ht in wavelenghts
fs 100.0 100.1 100.2 100.3 100.4 100.5 100.6 100.7
100.8 100.9 101.0
-77.7 -76.99 -78.68 -80.98 -84.25 -89.43 -95.78 -89.21 -84.10 -80.8
7 -78.60 -76.98

The free-space path loss over a 100 wavelenght path is calculated to be -82.15 dB. Adding 4.30 dB (2.15 dBi * 2) gives a calculation of -77.85 dB -- quite close to the -77.7 dB predicted in this case by EZNEC. Clearly, too, even in this "line of sight path," the effect of ground gain can be seen as the loss drops to slightly less than the free-space path loss.

Note the close comparison between the 100.0 and 101.0 figures (not surprising, I would expect a similar repeating pattern at 1 wavelenght height intervals). I didn't have time to do this coupled energy calculation for all different heights, but at a number of heights I tried at random, I saw very different amounts of coupling.

I also kept the heights contant at 100 wavelenghts and moved the receptor antenna from 1000 to 1001 wavelenghts away in -2 wavelenght increments. I found:

distance in wavelengths
1000 1002 1004 1006 1008 1010 1012 1014 1016 1018 1020
-77.0 -75.7 -74.7 -73.9 -73.7 -72.9 -72.6 -72.4 -72.3 -72.5 -72.7

Yes, the attenuation between the two antennas does indeed decrease as the distance increases, at least over the range calculated, showing the effect of the ground reflection that is taking place at the point between the two antennas. Although the variatio is small enough that most folks would consider this to be "far field," as one got closer to the antenna, one would see wider and wider swings, until one would see a large enough deviation from far field conditions to consider the point to be within the radiating near field. (One is no longer equidistant from the various parts of the antenna influencing the pattern, including its ground reflection.)

In all cases, both the far-field pattern (as previously calculated) of the half-wave dipole at ~100 wavelengths above ground and the calculated coupling between two half-wave dipoles located ~1000 wavelengths apart at ~100 wavelenghts above ground very much varied with height -- even at this height, the antennas do not act as if they are in free space, other than the fact that the mutual coupling between the antenna and the ground, or its image antenna (depends on how you want to see it) is not sufficient to change the antenna impedance as the height is varied..

Now, the effect with a very high-gain array will be much less, because the high-gain array generally directs << energy downward to interact with the earth, so your original statement may be reasonably valid in that context.

Now, under what circumnstances does one consider the ground reflection in dertermining performance? If one is discussing the performance of an antenna, under some circumstances, it is more clear to discuss that antenna performance in terms of free-space gain (dBi or dBd -- either is fine by me; they are precisely related to each other.) Under other circumstances where one is more concerned with the performance of the antenna in situ, the interaction of the antenna with the ground should, IMHO, be part of the evalaution of the antenna system. In cases of evaluating a communications system, including antenna and propagation between the two points, ALL aspects of the system should be considered. The valid reason to include ground gain with the antenna system is that one can then specify power in terms of EIRP (which WOULD include the real gain given by the ground under an antenna system) and path loss (free space or ionoshperic) and thus obtain a valid answer for received signal strength. One cannot obtain that from a free-space antenna gain under any circumstances under which the presence of ground affects the peformance of the antenna. From the models I have run, it appears that such interaction is part of many antenna systems.

When the "offer" was first made I seriously considered taking him up on it
and establishing a formal fund (lawyer, trust account, the whole enchilada)
figuring if only a percentage of those that thought he needed it would kick
in $10 or so, we could get him an evaluation and at least a couple of months
treatment just about anywhere.

Then the reality of the impossibility of the second part of his "offer" sunk
in and I dropped the idea.

Seems there is yet another part of the real world the Chipster has no
knowledge of; probably thinks you can get 8X10s of your head x-ray to prove
you have a brain...

Yes, but the reflection still takes place. Now, at significant height, the reflected energy will not affect the currents in the "driven element" antenna to any significant degree, but when you go arbitrarily far from the antenna >> the near field region, the reflected signal and the direct signal have traveled virtually the same distance, so they are attenuated by the same amount -- ie, they are at the same strength. Therefore, they can add up in or out of phase. The resultant "ground gain" would be 6 dB over perfect ground.

Are you saying that spending $10 to help someone get an evaluation and treatment is not a good thing unless you also get to share the results of that evaluation publically? It appears to me that the goal here is more focused on the sharing of the information publically. Let me ask you this, if you could get the evaluation and share it publically, but not offer any of the help and treatment you state is needed, would you still be "dropping the idea?" ...

Ed Hare, W1RFI wrote:
"Perhaps you have lost sight of the original premise--".

In my formula for the extent of the far field:
d = 3.18 a^2 / lambda.
a is the effective antenna area in square feet.
d is the extent of the near field in feet.

I calculated 86 feet for the extent of the near field for my rhombic at 3GHz. The wavelength is 1/3 foot.

My rhombic is on a 60-ft pole. This is about 180 wavelengths. There is no antenna height term in my formula because this is usually not relevant in microwaves. Relevant reflections usually come from miles away, well out of the near field.

What is the near field? It is a region near the antenna containing significant reactive energy in addition to radiant energy. The reactive energy returns to the antenna. The radiant energy does not return but continues on into the far field never to return. Strength of the reactive energy decays very rapidly. This means the near field can`t extend very far because it declines so rapidly by comparison with the radiation field that it soon pales by that comparison.

I think one would be hard pressed to detect any reactive energy from my little 3GHz rhombic at 22,777 feet (4.3 miles) in any direction.

My original premise was not to measure the pattern of an antenna over ground. It was almost the opposite. I had said that a 10-meter rhombic 60 feet over ground would have its gain affected by the ground. Then I said, that a scaled version for 3GHz would have nearly its 11 db free space gain at the same 60 foot altitude.

I think that statement is accurate. It agrees with my countless observations of microwave antennas on countless paths and antenna heights over the years.

Best regards, Richard Harrison, KB5WZI

Ed, I think you missed the point- Chip has put a condition on the deal that cannot be met- therefore, the intent of the givers is not even a consideration. It is a very sly "catch 22" situation.

An ethical therapist cannot divulge the results of his evaluation in this manner- therefore the requirement of publication cannot be met- therefore no matter how many of us put up, and no matter what our motivation is, we cannot arrive at a contract. It is not in our power. However, he can now say that he made an offer that we would not meet. We cannot even ignore the publication condition, because we did not include it.

Hope this helps.- Bill

No, I am saying that Chip attached a condition on his offer that is impossible
to be met. No reputable doctor would release such information to anyone.

I didn't initiate this, Chip did. I considered calling his bluff until
I realized it is impossible to meet his conditions.

Source record: 176800

As others have pointed out, it probably doesn't matter very much whether
you have a bit of mismatch.

Perhaps Roy could answer this question:
How good is the impedance match on a Tektronix SA over its rated
frequency range anyway? Is it any better than the minimal mismatch
between 75 and 50 ohms?

Another thing to consider is that if you are using a wideband antenna as
the source, it probably isn't exactly 50 ohms over its useful frequency
range either, so there is probably already a mismatch at the antenna terminals.

However, if you want to be exact, the easiest way to do the match would
be with a minimum loss resistive pad. In most applications using a
spectrum analyzer, additional loss is not a problem as long as you know
what that loss is.

Good luck!

Gray

As of 1991, the latest Tek catalog I have, Tek's lowest priced spectrum analyzer (2710) has a maximum input VSWR of 1.5:1 (with 10 dB or more attenuation), exactly what you'd get with a 75 to 50 ohm mismatch. However, it's specified to be flat within +/- 1.5 dB when driven with a precisely 50 ohm source, regardless of its input Z. So a different source impedance would degrade its flatness. Most of the other SAs are specified at 1.3:1 max up to 2.5 GHz.

I don't seem to recall going 'ballistic'. Its not part of who I am, so for you to characterize me in this way is more than a bit pejorative ,and over the top. In other words, here we go with yet more abuse.

Here are the facts, relative to events in recent weeks:

1) At least two individuals, who publicly post on this NG, have deliberately violated copyright law. This obligated me, as the injured party, to point out the trespass publicly, as their information on the availability was made publicly;

2) At least two other individuals have gone out of their way to make anti semitic-based comments and deliberately incite others, with false, misinformation-based comments. In fact, these 'blame the victim' tactics have had no small effect in inciting others. The bizarre and injurious trend of late has been to publicly label me as "mentally ill" and to go over the top by presenting this misinformation to those I work with; customers; and others. It has led to a change in my position ,which was a major change in my life, with very serious effects on my potential income and career progress. Basically it is a witch hunt.The objective is to alienate me , as well as 'label me'--falsely;

3) The top manager of a competing antenna company--which has previously demonstrating tangible and undesired interest in my affiliate-- has gone out of his to exploit a point of trivial scientific interest into one that deliberately tries to question my credibility and knowledge base.That person uses words like "fractal"; "arbitrary"; "random"; "electrically small"; and so on, in incorrect and /or misleading contexts with the intent to discredit me. It is noteworthy that this person has aided at least one individual in the aforementioned copyright violation;

4) The abuse goes on whether I am here or not. It is an obsession for some. I find it fundamnetally distasteful and beyond any acceptable level of human decency.

These, "SSB", are the facts. Nothing you can do or say can change them. The BEST you can do is be quiet and stop harassing me.

Cordially,

NC

NC:

I was really hoping that we had a deal. I was willing to live up to my word and not respond to your posts or bring up the subject of fractal antennas again. I assume that the terms of my deal were not acceptable to you.

You complain about people "attacking" you and then you turn around and do the same or worse to other people on the newsgroup. What happened in my case, did you just have to get in a few more jabs? A bit more libel and slander? Couldn't just let it end quietly?

Above, you claim that I try to question your credibility and knowledge base. I simply disagree with some of your technical statements. Here's what you actually say about me: "I am convinced that 99% of your arguments are predicated on incomplete understanding of some basic concepts."

Let's discuss some basic concepts and the technical knowledge base, of which you claim yourself to have superiority. In your previous post to me, you made the following technical claim regarding electrically small antennas:

>
"Wheeler defined electrically "small" for an antenna which fits within its radiansphere, which has diameter pi/2 radians. That is a 1/4 wavelength."
>

WRONG!!!

Harold Wheeler defines an electrically small antenna as one which occupies a volume of less than a radian sphere, i.e., a sphere of radius, r = wavelength / 2 pi. The diameter of this sphere would therefore be d = wavelength / pi, NOT, pi/2 radians. The radian sphere expressed in wavelengths r(wavelengths) = 1 / 2 pi (1 radian), NOT 1/8 wavelength. The diameter of the radian sphere is actually 2 radians (NOT pi/2 radians) if we consider that electrically, wavelength = 2 pi radians. It's called a radian sphere because it has a radius of 1 radian.

The radian sphere is actually a bit larger than you claim. However, there is more to the definition of electrically small antennas than just physical size or the radian sphere, i.e., current distribution in the case of electrically small loops. Most engineers assume that the radian sphere is an upper physical boundary and that an electrically small antenna is one such that 2 pi r << 1, where r is the radius of the antenna volume expressed in wavelengths.

Want to discuss knowledge base, technical credibility or understanding of basic concepts in more detail?

As suggested by others on the newsgroup, you should be more willing to engage in a discussion rather than dismissing others with claims of superior knowledge and understanding. It would also help if you didn't just dismiss others as being wrong simply because they disagree with you. Like ALL of US, you are sometimes wrong too.

Would you like to go back to the deal, or continue this foolishness?

Steve

How about these ones:

C.Puente, "Fractal Design of Multiband Antenna Arrays", Elec. Eng. Dept.
Univ. Illinois, Urbana-Champaign, ECE 477 term project, Dec.1993.

1993, November. The potentiallity of fractal arrays to become multifrequency
arrays is introduced by C.Puente at the University of Illinois at
Urbana-Champaign during a graduate course discussion.

1994. Some prelimar ideas on multiband fractal arrays are presented by
C.Puente at an URSI meeting in Las Palmas, Gran Canaria, Spain. Further work
on such ideas gives place to a paper that is submitted to the IEEE
Transactions on Antennas and Propagation in May 1994, and published in May
1996.

1995, May. After several months working on the invention of the Sierpinski
antenna, the Universitat Polit&#65533;cnica de Catalunya finally applies for the
patent on Fractal and Multifractal Antennas . Such results proved the
feasibility of fractals to become multiband antennas (i.e., antennas that
keep the same parameters at several frequency bands). A paper reporting the
first results is submitted to IEE Electronics Letters.

C.Puente, R.Pous, J.Romeu, X.Garc&#65533;a, "Antenas Fractales o Multifractales",
Invention Patent, n&#65533;: P-9501019. Presented at the Oficina Espa&#65533;ola de
Patentes y Marcas. Owner: Universitat Polit&#65533;cnica de Catalunya, May 1995.

Here you go, Romeo. More "research" than you ever wanted to show up on
rrap....

Enjoy. Maybe you'll finally actually learn something about the subject
and everyone else will see what a fraud you actually are...

A Brief Historical Review

The fractal design of antennas and arrays results from the blend of two aparently disjoint disciplines: electromagnetic theory and geometry. From the early spiral and log-periodic antennas developed in the early sixties by Carrel, Mayes et al, and from the works of Benoit Mandelbrot on fractal geometry, the fractal design of antennas appears as a natural way to explore for a multifrequency operation and for an antenna size reduction. This document reviews the development of such a novel concept and gives the reader some references for further reading.

Background

40's. L.J.Chu and H.Wheeler stablish a fundamental limit on the performance of small antennas.

60's. Several research teams at the University of Illinois at Urbana-Champaign, University of California and Ohio State University introduce the concept of frequency-independent antennas. The self-scaling concept gives place to the log-periodic dipole array and to the spiral antennas.

70's. B. Mandelbrot coins the term 'Fractal'. Such a name is used to describe a family of geometrical objects that defy the traditional rules of the Euclidean geometry. Later on, Mandelbrot states that such a weird fractal shapes are, in fact, among the most common forms in nature.

80's. D.Jaggard et al. coin the term 'Fractal Electrodynamics'. Electromagnetics and Fractal Geometry blend into a novel discipline. The interaction of fractal bodies and electromagnetic waves are investigated and some relationships between common fractal properties and the scattered electromagnetic waves are stablished.

90's. The first reported fractal multiband antennas are introduced by C.Puente et al. from the Universitat Politï¿½cnica de Catalunya. Also, the potentiallity of fractals to become small antennas is introduced by the same research team and by N.Cohen from the University of Boston.

Some Significant Milestones

1986-1993. Several authors theoretically investigate the relationships between fractal arrays and their array factors. Some fractal and array properties such as Fractal Dimension and Secondary Lobe Ratio are linked for the first time.

1993, November. The potentiallity of fractal arrays to become multifrequency arrays is introduced by C.Puente at the University of Illinois at Urbana-Champaign during a graduate course discussion.

1994. Some prelimar ideas on multiband fractal arrays are presented by C.Puente at an URSI meeting in Las

Palmas, Gran Canaria, Spain. Further work on such ideas gives place to a paper that is submitted to the IEEE Transactions on Antennas and Propagation in May 1994, and published in May 1996.

1995, May. After several months working on the invention of the Sierpinski antenna, the Universitat Politï¿½cnica de Catalunya finally applies for the patent on Fractal and Multifractal Antennas . Such results proved the feasibility of fractals to become multiband antennas (i.e., antennas that keep the same parameters at several frequency bands). A paper reporting the first results is submitted to IEE Electronics Letters.

1995, Summer. Some preliminar ideas on fractal small antennas are suggested by N.Cohen from the Boston University.

1996-1998. The first reported experimental results on fractal multiband antennas are published by the Electromagnetics & Photonics Engineering research team from the Universitat Politï¿½cnica de Catalunya.

1998. The Koch monopole becomes the first reported fractal small antenna that improves the features of some classical antennas in terms of bandwidth, resonance frequency and radiation resistance. Whether such antennas are bounded to the fundamental limits on small antennas is still a topic under investigation.

1998. The Fractal Team from the Electromagnetics & Photonics Engineering group (UPC), in cooperation with FractusTM the Fractal AntennasTM company from the Sistemas Radiantes F.Moyano S.A. group, develope the first commercial multiband fractal shape antennas for GSM + DCS cellular phone systems.

Just to be sure, this is addressed to:

Nathan Cohen, PhD
Chip, N1IR
NC

Hopefully that covers everyone:

Would you like to agree on the following deal:

.. I will not respond to any more of your posts on this topic nor will I
mention fractal antennas
again on this newsgroup under the following conditions:

1) You don't directly or indirectly respond to any of my posts.
2) You don't directly or indirectly mention or refer to me or my company.
3) You stop the insults.

Steve

>

Nope. The EL manuscript by Puente et al. was submitted in October 1995. It does
not reference the earlier Cohen article, published in August 1995.

>C.Puente, R.Pous, J.Romeu, X.Garcï¿½a, "Antenas Fractales o Multifractales",

Thank you for confirming my statements. I think it is important that one not get the false impression that Mr. Puente either worked on fractal antenna elements before me, nor that he published, nor produced prior art before me.

Clearly his work was on arrays, which has prior art in Kim and Jaggard's work in the mid 1980's and that of others as well. Later he switched to fractal elements.

Appreciate that!

Wes, N7WS wrote:
"The depth of the null is most certainly dependent upon the ground characteristics, but not the number of wave lengths above ground."

A wire over ground has an image in the ground. This makes an array of radiator plus image.

The resultant field at a point (n) is (En) and is the sum of the field of the radiator (the wire over ground), call the field: E1, and the field of the image, call this field: Ei. If these differ in phase by 180 degrees at point n, we have:
En = E1 + Ei on an angle of 180 degrees.

or: En = E1 - Ei

For a complete null Ei must equal E1.

Ei results from excitation by the wire over ground. Its intensity is definitely a function of the number of wavelengths that wire is above ground. The higher the wire the shallower the null trends.

Best regards, Richard Harrison, KB5WZI

Subject: $6 Deal=20

Date: 10-01-2000=20

Poster: Railsplitter

Message=20

A while back, I was browsing these newsgroups, just like you are now,=20
and came across an article similar to this that said you could make=20
thousands of CASH within weeks with only an initial investment of=20
$6.00 plus stamps! So I thought, "Yeah, right, this must be a scam!"=20
But like most of us I was curious and kept reading. It said that if=20
you send $1.00 to each of the 6 names and addresses listed in the=20
article, you could make thousands in a very short period of time. You=20
then place your own name and address at the bottom of the list at #6,=20
and post the article to at least 300 newsgroups. (There are about=20
32,000 of them out there and that's quite a large market pool). No=20
catch, that was it. Even though the investment was a measly $6, I had=20
three questions that needed to be answered before I could get involved=20
in this sort of thing.=20
1. IS THIS REALLY LEGAL?=20
I called a lawyer first. The lawyer was a little sceptical that I would=20

actually make any CASH but he said it WAS LEGAL if I wanted to try it.=20
I told him it sounded a lot like a chain letter but the details of the=20
system (SEE BELOW) actually made it a legitimate legal business.=20
2. IS OK WITH THE POST OFFICE OR IS IT MAIL FRAUD? I called them:=20
1-800-725-2161 and they confirmed THIS IS ABSOLUTELY LEGAL! (See 18,=20
h sections1302 NS 1341 of Postal Lottery Laws). This clarifies the=20
program of collecting names and addresses for a mailing list.=20
3. IS IT RIGHT? Well, everyone who sends me a buck has a good chance of=20
getting A LOT of CASH ... a much better chance than buying a lottery=20
ticket!!!=20
So, having these questions answered, I invested EXACTLY $7.92 ... six=20
$1.00 bills and six 32 cent postage stamps ... and boy am I glad I did!=20
Within 7 days, I started getting CASH in the mail! I was shocked! I=20
figured it would end soon and didn't give it another thought. But the=20
CASH continued coming in. In my first week I made between $20 to $30.=20
By the end of the second week I had a made a total of $1,000.00. In the=20
third week I had over $10,000.00 and it was still growing. This is now=20
my fourth week and I have made a total of just over $42,000 and it's=20
still coming in ..... It's certainly worth $6.00 and 6 stamps !!!=20
Also, make sure you print a copy of this article NOW, so you can get=20
the information off of it as you need it. I promise you that if you=20
follow the directions exactly, that you will start making more CASH=20
than you thought possible by doing something so easy!=20
Suggestion: Read this entire message carefully! (print it out or=20
download it.) Follow the simple directions and watch the CASH come in!=20
It's easy. It's legal. And your investment is only $6.00 (plus postage)=20
IMPORTANT: This is NOT a rip-off; it is NOT indecent; it is NOT=20
illegal; and it is virtually no risk - it really works!!!! If all of=20
the following instructions are adhered to, you will receive=20
extraordinary dividends.=20
PLEASE NOTE:=20

Please follow these directions EXACTLY, and $50,000 or more can be=20
yours in 20 to 60 days. This program remains successful because of the=20
honesty and integrity of the participants. Please continue its success=20
by carefully adhering to the instructions. You will now become part of=20
the Mail Order business. In this business your product is not solid and=20
tangible, it's a service. You are in the business of developing Mailing=20
Lists. Many large corporations are happy to pay big bucks for quality=20
lists. However, the CASH made from the mailing lists is secondary to=20
the income which is made from people like you and me asking to be=20
included in that list.=20
Here are the 4 easy steps to success:=20
STEP 1: Get 6 separate pieces of paper and write the following on each=20
piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00=20
bills and place ONE inside EACH of the 6 pieces of paper so the bill=20
will not be seen through the envelope (to prevent thievery). Place one=20
paper in each of the 6 envelopes and seal them. You should now have 6=20
sealed envelopes, each with a piece of paper stating the above phrase,=20
your name and address, and a $1.00 bill. What you are doing is creating=20
a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate=20
service and you are paying for it! Like most of us I was a little=20
skeptical and a little worried about the legal aspects of it all. So I
checked it out with the U.S. Post Office (1-800-725-2161) and they
confirmed that it is indeed legal! Mail the 6 envelopes to the
following addresses:
#1) M. Weber=20
801 Oaklands Dr=20
Round Rock, TX 78681=20
#2) S. Patti=20
1808 Ponderosa St.
Cocoa, Fl.,32926
#3) Gill=20

58 Moross

Mt. Clemens Mi. 48043=20

#4) Ryan Dick

7603 Canyon Dr.

Meridian, ID 83642

#5) Y.S.

2702 A Jenner Dr.

Baltimore, MD 21209

#6) D. Sims

905 Burning Bush Drive

Loganville, GA 30052

step 2: Now take the #1 name off the list that you see above, move the =
other=20

names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number =
6 on=20

the list.

STEP 3: Change anything you need to, but try to keep this article as=20

close to original as possible. Now, post your amended article to at=20

least 300 newsgroups. (I think there are close to 32,000 groups) All=20

you need is 300, but remember, the more you post, the more CASH you=20

make! This is perfectly legal! If you have any doubts, refer to 18=20

Sec. 1302 & 1341 of the Postal lottery laws. Keep a copy of these=20

steps for yourself and, whenever you need CASH, you can use it again,=20

and again.=20

PLEASE REMEMBER that this program remains successful because of the=20

honesty and integrity of the participants and by their carefully=20

adhering to the directions. Look at it this way. If you are a person=20

of integrity, the program will continue and the CASH that so many=20

others have received will come your way.=20

NOTE: You may want to retain every name and address sent to you,=20

either on a computer or hard copy and keep the notes people send you.=20

This VERIFIES that you are truly providing a service. (Also, it might=20
be a good idea to wrap the $1 bill in dark paper to reduce the risk of=20
mail theft.) So, as each post is downloaded and the directions=20
carefully followed, six members will be reimbursed for their=20
participation as a List Developer with one dollar each. Your name will=20
move up the list geometrically so that when your name reaches the #1=20
position you will be receiving thousands of CASH in CASH!!! What an=20
opportunity for only $6.00 ($1.00 for each of the first six people=20
listed above) Send it now, add your own name to the list and you're in=20
business!=20
---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS=20
Step 1) You do not need to re-type this entire letter to do your own=20
posting. Simply put your cursor at the beginning of this letter and=20
drag your cursor to the bottom of this letter, and select 'copy' from=20
the edit menu. This will copy the entire letter into the computer's=20
memory.=20
Step 2) Open a blank 'notepad' file and place your cursor at the top=20
of the blank page. From the 'edit' menu select 'paste'. This will paste=20
a copy of the letter into notepad so that you can add your name to the=20
list.=20
Step 3) Save your new notepad file as a .txt file. If you want to do=20
your postings in different settings, you'll always have this file to=20
go back to.=20
Step 4) Use Netscape or Internet explorer and try searching for=20
various newsgroups (on-line forums, message boards, chat sites,=20
discussions.)=20
Step 5) Visit these message boards and post this article as a new=20
message by highlighting the text of this letter and selecting paste=20
from the edit menu. Fill in the Subject, this will be the header=20
that everyone sees as they scroll through the list of postings in a=20
particular group, click the post message button.=20

You're done with your first one! Congratulations...THAT'S IT! All you=20
have to do is jump to different newsgroups and post away, after you=20
get the hang of it, it will take about 30 seconds for each newsgroup!=20
**REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE=20
MORE CASH YOU WILL MAKE!! BUT YOU HAVE TO POST A=20
minimum of 300**
That's it! You will begin receiving CASH from around the world within=20
days! You may eventually want to rent a P.O.Box due to the large=20
amount of mail you will receive. If you wish to stay anonymous, you=20
can invent a name to use, as long as the postman will deliver it.=20
JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.=20
Now the WHY part:=20
Out of 300 postings, say I receive only 7 replies (a very low example).=20
So then I made $7.00 with my name at #6 on the letter. Now, each of the=20
7 persons who just sent me $1.00 make the MINIMUM 300 postings, each=20
with my name at #5 and only 7 persons respond to each of the 7 original=20
7, that is another $49.00 for me, now those 49 each make 300 MINIMUM=20
posts with my name at #4 and only 7 replies each, I will bring in an=20
additional $343.00! Now, those 343 persons turn around and post the=20
MINIMUM 300 with my name at #3 and only receive 7 replies each, I will=20
make an additional $2401.00! OK, now here is the fun part, each of=20
those 2401 persons post a MINIMUM 300 letters with my name at #2 and=20
they each only receive 7 replies, that just made me $16,807.00!!!=20
Those 16807 persons will all deliver this message to 300 newsgroups=20
with my name at #1 and if still 7 persons per 300 Newsgroups react I=20
will receive $117,649.00! With an original investment of only $6.00!=20
And some stamps. AMAZING! When your name is no longer on the list, you=20
just take the latest posting in the newsgroups, and send out another=20
$6.00 to names on the list, putting your name at number 6 again. And=20
start posting again. The thing to remember is: do you realize that=20
thousands of people all over the world are joining the internet and=20

reading these articles everyday? JUST LIKE YOU are now!! So, can you=20
afford $6.00 and see if it really works?? I think so...=20
People have said, "what if the plan is played out and no one sends you=20
the CASH? So what! What are the chances of that happening when there=20
are tons of new honest users and new honest people who are joining the=20
internet and newsgroups everyday and are willing to give it a try?=20
Estimates are at 20,000 to 50,000 new users, every day, with thousands=20
of those joining the actual internet.=20
Remember, play FAIRLY and HONESTLY and this will really work.=20
** By the way, if you try to deceive people by posting the messages=20
with your name in the list and not sending the CASH to the rest of the=20
people already on the list, you will NOT get as much. Someone I talked=20
to knew someone who did that and he only made about $150.00, and that's=20
after seven or eight weeks! Then he sent the 6 $1.00 bills, people=20
added him to their lists, and in 4-5 weeks he had over $10k.=20
This is the fairest and most honest way I have ever seen to share the=20
wealth of the world without costing anything but our time!!! You also=20
may want to buy mailing and e-mail lists for future CASH. Make sure=20
you print this article out RIGHT NOW! Also, try to keep a list of every=20
one that sends you CASH and always keep an eye on the newsgroups to=20
make sure everyone is playing fairly. Remember, HONESTY IS THE BEST=20
POLICY. You don't need to cheat the basic idea to make the CASH!! GOOD=20
LUCK to all and please play fairly and reap the huge rewards from this,=20
which is tons of extra CASH.=20
Please remember to declare your extra income. Thanks once again...=20
"People have asked me if this is really legal. Well, it is! You are=20
using the Internet to advertise your business. What is that business?=20
You are creating a mailing list of people who are interested in home=20
based computer and online business and methods of generating income at=20
home. Remember, people send you a small fee to be added to your mailing=20
list. It is legal. what will you do with your list of thousands of=20

names?=20

That's up to you." So, build your mailing list, keep good accounts,=20

declare the income and pay your taxes. By doing this you prove your=20

business intentions. Keep an eye on the newsgroups and when the cash=20

has stopped coming (that means your name is no longer on the list),=20

you just take the latest posting at the newsgroups, send another $6.00=20

to the names stated on the list, make your corrections (put your name=20

at #6) and start posting again.=20

NOTES:=20

*1. In some countries, the export of the country's exchange is illegal.=20

But you can get the license to do this from the post office, explaining=20

the above statements (that you have an online business, etc. You may=20

have to pay an extra tax, but that's OK, the amount of the incoming=20

CASH is HUGE! And as I said, a few countries have that restriction.=20

*2. You may want to buy mailing and e-mail lists for future CASH. (Or=20

Database or Spreadsheet software.)=20

*3. If you're really not sure or still think this can't be for real,=20

please print a copy of this article and give it to someone who really=20

needs the CASH, and see what happens.=20

*4. You will start getting responses within 1-2 weeks, it depends.=20

ALSO REMEMBER=20

SEND YOUR $1 OUT TO EVERYONE ON THE LIST,=20

EVEN IF THEY ARE NOT FROM THE U.S.=20

WHAT ARE YOU WAITING FOR???=20

$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!=20

GOOD LUCK!!!=20

Date: 10-01-2000

Poster: Railsplitter

Message

A while back, I was browsing these newsgroups, just like you are now, =

and came across an article similar to this that said you could make =

thousands of CASH within weeks with only an initial investment of =

$6.00 plus stamps! So I thought, "Yeah, right, this must be a scam!" =

But like most of us I was curious and kept reading. It said that if =

you send $1.00 to each of the 6 names and addresses listed in the =

article, you could make thousands in a very short period of time. You =

then place your own name and address at the bottom of the list at #6, =

and post the article to at least 300 newsgroups. (There are about =

32,000 of them out there and that's quite a large market pool). No =

catch, that was it. Even though the investment was a measly $6, I had =

three questions that needed to be answered before I could get =
involved

in this sort of thing.

1. IS THIS REALLY LEGAL?

I called a lawyer first. The lawyer was a little sceptical that I =
would

actually make any CASH but he said it WAS LEGAL if I wanted to try =
it.

I told him it sounded a lot like a chain letter but the details of =
the

system (SEE BELOW) actually made it a legitimate legal business.

2. IS OK WITH THE POST OFFICE OR IS IT MAIL FRAUD? I called them: =

1-800-725-2161 and they confirmed THIS IS ABSOLUTELY LEGAL! (See 18, =

h sections1302 NS 1341 of Postal Lottery Laws). This clarifies the =

program of collecting names and addresses for a mailing list.

3. IS IT RIGHT? Well, everyone who sends me a buck has a good chance =
of

getting A LOT of CASH ... a much better chance than buying a lottery =

ticket!!!

So, having these questions answered, I invested EXACTLY $7.92 ... six =

$1.00 bills and six 32 cent postage stamps ... and boy am I glad I =
did!

Within 7 days, I started getting CASH in the mail! I was shocked! I =

figured it would end soon and didn't give it another thought. But the =

CASH continued coming in. In my first week I made between $20 to $30. =

By the end of the second week I had a made a total of $1,000.00. In =
the

third week I had over $10,000.00 and it was still growing. This is =
now

my fourth week and I have made a total of just over $42,000 and it's =

still coming in ..... It's certainly worth $6.00 and 6 stamps !!! =

Also, make sure you print a copy of this article NOW, so you can get =

the information off of it as you need it. I promise you that if you =

follow the directions exactly, that you will start making more CASH =

than you thought possible by doing something so easy!

Suggestion: Read this entire message carefully! (print it out or

download it.) Follow the simple directions and watch the CASH come =
in!

It's easy. It's legal. And your investment is only $6.00 (plus =
postage)

IMPORTANT: This is NOT a rip-off; it is NOT indecent; it is NOT

illegal; and it is virtually no risk - it really works!!!! If all of =

the following instructions are adhered to, you will receive

extraordinary dividends.

PLEASE NOTE:

Please follow these directions EXACTLY, and $50,000 or more can be =

yours in 20 to 60 days. This program remains successful because of =
the

honesty and integrity of the participants. Please continue its =
success

by carefully adhering to the instructions. You will now become part =
of

the Mail Order business. In this business your product is not solid =
and

tangible, it's a service. You are in the business of developing =
Mailing

Lists. Many large corporations are happy to pay big bucks for quality =

lists. However, the CASH made from the mailing lists is secondary to =

the income which is made from people like you and me asking to be =

included in that list.

Here are the 4 easy steps to success:

STEP 1: Get 6 separate pieces of paper and write the following on =
each

piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US =
$1.00

bills and place ONE inside EACH of the 6 pieces of paper so the bill =

will not be seen through the envelope (to prevent thievery). Place =
one

paper in each of the 6 envelopes and seal them. You should now have 6 =

sealed envelopes, each with a piece of paper stating the above =
phrase,

your name and address, and a $1.00 bill. What you are doing is =
creating

a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate =

service and you are paying for it! Like most of us I was a little =

skeptical and a little worried about the legal aspects of it all. So =
I

checked it out with the U.S. Post Office (1-800-725-2161) and =
they

confirmed that it is indeed legal! Mail the 6 envelopes to the

following addresses:

#1) M. Weber

801 Oaklands Dr

Round Rock, TX 78681

#2) S. Patti

1808 Ponderosa St.

Cocoa, Fl.,32926

#3) Gill

58 Moross

Mt. Clemens Mi. 48043

#4) Ryan Dick

7603 Canyon Dr.

Meridian, ID 83642

#5) Y.S.

2702 A Jenner Dr.

Baltimore, MD 21209

#6) D. Sims

905 Burning Bush Drive

Loganville, GA 30052

step 2: Now take the #1 name off the list that you see above, move =
the other=20

names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as =
number 6 on=20

the list.

STEP 3: Change anything you need to, but try to keep this article as =

close to original as possible. Now, post your amended article to at =

least 300 newsgroups. (I think there are close to 32,000 groups) All =

you need is 300, but remember, the more you post, the more CASH you =

make! This is perfectly legal! If you have any doubts, refer to 18 =

Sec. 1302 & 1341 of the Postal lottery laws. Keep a copy of these =

steps for yourself and, whenever you need CASH, you can use it again, =

and again.

PLEASE REMEMBER that this program remains successful because of the =

honesty and integrity of the participants and by their carefully

adhering to the directions. Look at it this way. If you are a person =

of integrity, the program will continue and the CASH that so many =

others have received will come your way.

NOTE: You may want to retain every name and address sent to you,

either on a computer or hard copy and keep the notes people send you. =

This VERIFIES that you are truly providing a service. (Also, it might =

be a good idea to wrap the $1 bill in dark paper to reduce the risk =
of

mail theft.) So, as each post is downloaded and the directions

carefully followed, six members will be reimbursed for their

participation as a List Developer with one dollar each. Your name =
will

move up the list geometrically so that when your name reaches the #1 =

position you will be receiving thousands of CASH in CASH!!! What an =

opportunity for only $6.00 ($1.00 for each of the first six people =

listed above) Send it now, add your own name to the list and you're =
in

business!

---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS

Step 1) You do not need to re-type this entire letter to do your own =

posting. Simply put your cursor at the beginning of this letter and =

drag your cursor to the bottom of this letter, and select 'copy' from =

the edit menu. This will copy the entire letter into the computer's =

memory.

Step 2) Open a blank 'notepad' file and place your cursor at the top =

of the blank page. From the 'edit' menu select 'paste'. This will =
paste

a copy of the letter into notepad so that you can add your name to =
the

list.

Step 3) Save your new notepad file as a .txt file. If you want to do =

your postings in different settings, you'll always have this file to =

go back to.

Step 4) Use Netscape or Internet explorer and try searching for

various newsgroups (on-line forums, message boards, chat sites,

discussions.)

Step 5) Visit these message boards and post this article as a new =

message by highlighting the text of this letter and selecting paste =

from the edit menu. Fill in the Subject, this will be the header

that everyone sees as they scroll through the list of postings in a =

particular group, click the post message button.

You're done with your first one! Congratulations...THAT'S IT! All you =

have to do is jump to different newsgroups and post away, after you =

get the hang of it, it will take about 30 seconds for each newsgroup! =

**REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE

MORE CASH YOU WILL MAKE!! BUT YOU HAVE TO POST A

minimum of 300**

That's it! You will begin receiving CASH from around the world within =

days! You may eventually want to rent a P.O.Box due to the large

amount of mail you will receive. If you wish to stay anonymous, you =

can invent a name to use, as long as the postman will deliver it. =

JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.

Now the WHY part:

Out of 300 postings, say I receive only 7 replies (a very low =
example).

So then I made $7.00 with my name at #6 on the letter. Now, each of =
the

7 persons who just sent me $1.00 make the MINIMUM 300 postings, each =

with my name at #5 and only 7 persons respond to each of the 7 =
original

7, that is another $49.00 for me, now those 49 each make 300 MINIMUM =

posts with my name at #4 and only 7 replies each, I will bring in an =

additional $343.00! Now, those 343 persons turn around and post the =

MINIMUM 300 with my name at #3 and only receive 7 replies each, I =
will

make an additional $2401.00! OK, now here is the fun part, each of =

those 2401 persons post a MINIMUM 300 letters with my name at #2 and =

they each only receive 7 replies, that just made me $16,807.00!!! =

Those 16807 persons will all deliver this message to 300 newsgroups =

with my name at #1 and if still 7 persons per 300 Newsgroups react I =

will receive $117,649.00! With an original investment of only $6.00! =

And some stamps. AMAZING! When your name is no longer on the list, =
you

just take the latest posting in the newsgroups, and send out another =

I tried modeling it with EZNEC. The bottom two bands modeled per the article,
but the top band modeled with an impedance (at resonance) of about 100 Ohms
instead of the claimed nominal 50 Ohms.

Anyone else try modeling this and get similar results, or did I host the
model?

Jim Pennino

If I understand you, was Puente's earlier work on a fractal arrays simply a
fractal array geometry of non-fractal elements? I.E. fractal in terms of
element positioning and location? I would need to see the references to
appreciate the distinction. Aside from the log-periodic antennas, then
perhaps your work was the first published article presentation of fractal
"elements". I have no problem agreeing with you when you are correct nor
do I have any problem giving credit where credit is due. There is one more

reference I have to track down - it may or may not refer to your work.

I still disagree with some of your claims on the unique properties of fractal antennas (simply because of geometry) versus non-fractal geometries. I also think your claim of having "invented the field" is a bit of a stretch given the extensive prior work and references quoted at the web link.

Civilized discussions always welcome,

Steve

The forwarding from ArrowAntenna.com to the web page on AOL
(http://Members.aol.com/Arrow146/index.html)
has been down for awhile.
Finely got it back up yesterday.

In a few months I hope to do some up grading to the site.
Some new products.......

A new wide band OSJ Antenna for VHF & Marine band.
Covers 150 MHz. to 162 MHz.

A New ADF Antenna, Adjustable 3 element handheld Yagi for DF.
Adjustable from 110 MHz. to 510 MHz.

Dimensions (element length, diameter and spacing) all affect the
performance characteristics of a beam - F/B ratio, F/Side ratio,
Gain, bandwidth. For 2M repeaters, the antenna should be vertically
polarized, and you want all the elements in front of the mast.

Yes.

I.E. fractal in terms of
>element positioning and location? I would need to see the references to
>appreciate the distinction. Aside from the log-periodic antennas, then
>perhaps your work was the first published article presentation of fractal
>"elements".

I have not seen anything that pre-dates it--for deterministic or substantially deterministic elements. As I have clearly stated, RANDOM fractal elements had been around since Landstorfer's work. However, from a --science--as opposed to inventive viewpoint, I was also the first to recognize and articulate those RANDOM forms as fractal element antennas.

Concurrent with that, Valdivia did work on lightning as random fractal antennae.

I have no problem agreeing with you when you are correct nor

Yes; and as I have stated, the 'issue' appears to be on key words such as "fractal"; "electrically small"; " random"; ad nauseum.

>I also think your claim of having "invented the field" is a bit of a stretch

I am an avid outdoors man and enjoy many outdoor activities. I actually spend time in the woods, not just the 'paved' hiking trails used by our liberal urbanites. America is still very conservative, yet the liberal big cities seem to try to represent America. Just watch the nightly news to see that the view of america comes from crowded cities plagued with crime, crowding and socialistic attitudes.

Why should we listen to those big cities? Why should an encroaching urban area, coerce the suburbanite to yield to restrictive antenna convenants, complain of the gun range noise they moved next to, or complain that the dairy farm stinks?

Many urbanites have no clue what the real world is like. I see urbanites voting on hunting, gun, trapping, land-use issues and continuing to restrict the rights of people who actually own, use and understand the outdoors. Why should urbanites that have totally destroyed their local environment, paving everything in site, congesting the streets with their busses have any say about the farmer, gold miner, radio amateur outside their ruined cities. If they could return their city to a condition that even came close to the suburbanite, then I might consider their voting opinion more valid. In the mean time, I think that we would have to agree that most liberal urbanites seem to want us to 'clean up our act' while they continue living as they see fit in their rights restricted, environmentally damaged, bus clogged city. These liberals seem to be the ones who don't want to let me vote, but want to vote for me and tell me how I should run my life.

Let's put it another way, do you think that either Dan Rather or Tom Brocaw really understand the issues that they spout from the teleprompter while showing an edited newsclip. Their Democrat mouthpiece, unfortunately, is thought to be objective or truthful my the many Americans that spend their day working to support their wonderful families and don't have the time to research the truth.

Although born and raised in the North, I trust that Texas farmer who owns land and invests wisely. As far as 'no vote'... It truly is Bush who trusts the American people, not a big government who divides the people, causing racial and economic fighting, then while we are distracted bickering, take more rights from us. I would ask you to think a bit more about your position. It may have been formed, not by you, but by the liberal media.

Now, let's work to keep our ham bands in the next WARC, to keep and enhance PRB-1, keep our RF power capabilities and our right to mobile communications.

And a quick word of advice.... If you don't like some of the things Bush has done, just use some of the same excuses that you used to defend Clinton/Gore. At least you would appear consistent.

That's quite fine from my perspective. If your papers were the first to discuss fractal elements as antennas, fine by me. Kudos to you. This was never the original point of our disagreement.

Our disagreements on the *unique* benefits of fractal geometry (self-similar structures as you defined in a recent post) versus non-fractal geometry, Kraus's definition of electrically small and Wheeler's definition of electrically small, remain unaffected at this point. Quite honestly, its pointless to discuss here any further, so I would like to end the discussion and will do so if you respect my wishes and do not discuss or refer to me or my company publicly in anyway.

Can you respect these wishes?

>pattern is concerned.

It seems to me that the pattern EZNEC has computed is not consistent with
a far-field pattern at infinite distance. At infinity, with a perfectly
reflecting ground, you would expect to see a peak intensity which is
constant with respect to elevation angle, with perfect nulls at all
elevations. Instead the peaks decrease with increasing elevation angle,
and the nulls get shallower. At 90 degrees (i.e. straight up) the
null looks like it is only 11 or 12 dB (?) down from the peak, which
strongly suggests that the pattern measurement distance is not all that
large compared to the height of the antenna above the reflecting ground.

In fact, if I'm doing the math right (unlikely), an 11 or 12 dB difference
between the peaks and null at 90 degrees suggests the pattern is being
measured at somewhere on the order of 4350 or 5500 wavelengths from the
antenna. At 14.1 MHz this would be about 100 kilometers, which is not
that large compared to the 3.8 km height of the antenna. While this may
be off, you can also test the hypothesis by moving the antenna up and
down and observing changes in the pattern. There shouldn't be any if
the pattern is being evaluated at infinity (assuming you keep the
antenna high enough that the ground is still in its far-field, and
move it up or down by wavelength multiples), but at a finite distance
the vertical null should get deeper as you move closer to ground and
shallower as you move away.

My NEC documentation is at home, but if NEC is really computing the
far-field pattern at infinity I'd very much like to understand how
it gets the pattern it does in this case.

Let me get this straight:

I didn't ask you to respond--incorrectly--when I pointed out that the Puente work is not the first with fractal elements. You volunteered to do so; I, cordially, corrected and explained, and now you want to stop.

Is that it?

If so, the answer is obvious: sure!

Chuck,

Regarding antenna height and your 1 wavelength recommendation: I'm about to erect a 5 band, 2 element quad... which is essentially an 18 foot square, 3 dimensional box. Should I be placing the bottom, center, or top of this box at 64 feet -- or just take an "as high as possible" attitude?

Chris Vancil wrote:
"I have a Nutex Communications Video Set with a range of about 700 feet and need to increase the receiving range by about 150 times that."

Path loss at 700 feet is about 87 db. Path loss at 29 miles is about 130 db. You need to make up about 43 db of loss due to lengthening the path.

Suppose you already have 3.5 db gain over an isotropic at each. You then need antennas on each end of the longer path which have about 25 db gain over an isotropic.

3.3-ft minimum diameter dishes are required (55% dish efficiency is assumed).

The 700-ft range you quote may give only -90 dbm at the receiver input. That would probably include a lot of snow.

A 20-mi path will also have fades.

So, you really need a lot more dish than 3.3 ft dia on each end.

You also need a lot of antenna height on each end, even if there are no obstructions, because the earth`s surface is curved. About 50 feet of elevation on each end will give line of sight clearance with no allowance for Fresnel zone clearance. Adjacent Fresnel zones produce some wave cancellation unless additional clearance is provided on the path.

A 6-ft dish has about 30 db gain over an isotropic at 2.4 GHz. A 10-ft dish has about 35 db gain over an isotropic at 2.4 GHz.

Microwave relay of television signals requires a license in the USA. The frequencies allocated for this are several times the catch-all 2.4 GHz frequencies used for all maner of appliances. TV relay frequencies get more gain wtih smaller dishes but suffer more propagation problems.

Best regards, Richard Harrison, KB5WZI

I'm not sure what parameters were used in calculating the pattern Ed shows. I ran a 20 meter dipole up 12,656 feet (180 wavelengths) over perfect ground, and got much deeper nulls -- around 35 dB relative to the peaks. This was using the minimum step size of 0.1 deg. I'm not surprised to see imperfect nulls, since even with 0.1 degree step size, the precise angle necessary for a perfect null may seldom or never be used by the program. In addition, the limitations of numerical precision limit the program's ability to calculate perfect zeros at precise angles. However, nulls should be deeper than shown in Ed's plot. DOS versions of EZNEC show the same result as EZNEC 3.0. The peculiar nulls in Ed's pattern might possibly be due to the jpg file conversion.

This calculation can easily be made with the EZNEC demo program, as well as the standard version. Start with the BYDipole.ez model. Change Ground Type to Perfect. Click Step Size and change to 0.1. Then click Wires to open the Wires Window, and change the Z coordinate of each wire to 12656. Finally, click FF Plot to see the pattern. You might want to maximize the plot display window (by clicking the button with the square symbol in the upper right corner) in order to see the details better. The variation in null depth is, I believe, mostly due to the step size limitation of 0.1 degree. The free demo program is available at http://eznec.com.

If anyone sees a plot with the limited depth nulls as in Ed's plot, please attach the .EZ file to an email message to me -- I'd be interested in seeing how it can happen.

Correction. That should be a 1.7, not 3.7 dB reduction, assuming a 75 ohm source impedance. I neglected to take the source impedance into account in doing the calculation.

Thanks to Bart Rowlett, WB6HQK, for pointing out the error.

The last sentence should read "Then click Wires to
open the Wires Window, and change the Z coordinate of each wire END to
12656."

It's just one of those days. . .

"The model is not wrong. The effect of a reflection off perfect earth is exactly the same as the effect of feeding another antenna, located 2H below the first antenna in free space, where H is the height of the antenna over ground."

With equal power to both antennas?

That doesn`t compute. You are directly feeding the actual balanced radiator 180 wavelengths above ground. The earth image is parasitically excited with only tiny coupling between the two antennas.

Hi OM,

You are too kind.

Let's all remember that time, oh so long ago (a month or two?) where numerous claims of technical issues protected by patent pending were being made?

Talk about topics dropped like a hot potato.

The patent process is one of full disclosure where no one can claim ignorance of the outcome. If the PTO sends you a letter of allowance, you know exactly what will be published, there is no justification for making claims that are unsupported by the process already fully revealed. The PTO expresses quite clearly that the usage of Patent Pending is a felony, a FRAUD, if no such coverage exists.

To judge by the refusal to accept this as a mental aberration can only lead one to believe that these frauds were willful and deliberate - and they were, as part of an act of hostility and open contempt of our members here in this forum. If this practice were exposed to his peers, it would be professional suicide. But such will never happen unless fraudtenna makes a point of circulating this message to accumulate damages to then falsely claim the privilege of the injured party (it is our group who is the injured party and this manipulation of the status of "victim" by fraudtenna is self-debasement).

Thus you see why some topics are never broached again.

You might have a look at Harry's Homebrew page:

http://hem2.passagen.se/sm0vpo/

he has some small antenna ideas there for 20M. I operate out of an apartment myself. The balcony here is large enough to fit up to a 15M dipole (with some bending) and I have used a 20M dipole drooped over the sides like a double inverted 'L'. After dark I toss out a wire dipole for the lower bands into the trees below. Your height will be a benefit and will compensate for a compromise antenna. What band(s) are you planning on operating on? Hope that provides some help or inspiration.

Actually, Chip, Nathan, NC, whatever you're calling yourself at the present time, you have gone "ballistic" on me in a post a couple months ago. I asked a direct question about the side and rear rejection of one of your fractal beams, and you went so far as to call me a bliterhing idiot (paraphrasing here), and that if I couldn't figure that out from the information on fractenna.com, specifically the dbi, I was such an idiot that I wasn't worth your time... I'd call that verbally ballisitic.

It's taken over two months for you to respond to a post of mine directly addressing you.... Wonder what the reasoning behind that is...

Hit dejanews and look it up. I don't have the time to prove to you what I and the other members of this newsgroup already know to be true.

Thats a bug catcher. Been around for years, and I still think overall
the best you can use. I prefer them over screwdrivers for outright brute
performance. Usually the coil is a little better on the bugcatchers, and
also you can add a capacity hat which will let you use less turns of the
coil to tune. Less coil loss.

> I know that in my CB radio days, the 108" whip was the best thing

Sure, a loaded short vertical of any type will never be as good as the
full 1/4 wave whip. Only in very rare cases might the loaded whip do
better due to a better ground plane from being on top of the car.

Define a "simple" duplexer.. A duplexer allows a receiver and transmitter
to share
a common system. A good duplexer will allow to as low as 400KHz
separation on two meters.

I think there is some confusion here regarding the defination of what a
duplexer
is. In my mind, VHF/VHF duplexer is a BP/BR or hybrid ring system using
four to six cavities to achieve 90 dB of port to port isolation.

Ah, average ground would do it. The ground absorption is greater at
near-normal angles of incidence than at glancing angles, so the nulls would
get shallower at higher elevation angles.

Hi,
I read in a post the other day that MFJ sold a 33' telescoping fiberglass mast model MFJ 1910 (I think) for around $80. Can't find it in the catalog, mfj web site or anywhere else. Saw one at Dayton that a German was selling, and I think Kanga handles them in The US, but they are around $100. I think this would be great for field day or putting up a quickie "stealth" antenna under cover of darkness that could be taken down real quick. Anybody point me to a source?

No, not "definitely". This also depends on where you measure the
combined radiation pattern. If `h' is the height of the wire above
perfect ground, and `R' is the distance from the wire at which you are
measuring the radiation pattern, then in the (worst case) vertical
direction from the wire we have

E1/Ei = (R + 2h) / R = 1 + (2h / R)

If R is very large compared to 2h, then 2h/R->0 and E1 is equal to
Ei. If R->infinity, which is apparently where NEC computes its far-field
patterns, then the ratio E1/Ei is always 1 and does not depend on the
(finite) value of `h'.

Actually, I think your way doesn't compute with respect to conservation
of energy. With one antenna and perfect ground, all energy radiated
by the antenna ends up in one hemisphere, with the energy radiated
downward being reflected back up by the ground.

With two antennas in free space one gets the same pattern, but in both
hemispheres. This requires exactly twice the power, so the second antenna
that replaced the ground had better have the same power input as the original
antenna.

This should suggest that ground reflection doesn't depend much on
parasitic coupling (though parasitic coupling may affect the resulting
pattern if the first antenna is close enough to the ground).

Wellllll...Yes and no.
If nothing bothers it, and there are no stones to nick the jacket in the dirt then straight PVC works fine, but in stonly soil it pay to use cable designed for direct burial which has a filler in the braid to prevent the migration of water.

Particulary here in the north, with stony soil and the freeze and thaw cycles, PVC is likely to get a nick in the jacket which will allow water to migrate along the braid. That will eventually destroy the braid.

Having said all that, I've used straight PVC in direct burial for years (with no problem), but as of late I've been installing it in conduit. Lots easier if you want to change, add, or what ever. And ... you can even make changes while the ground is frozen, flooded, covered with snow, or whatever. Also, the plastic conduit is relatively cheap even for 3". Normally 2" would be plenty sufficient.

Actually I prefer metal conduit, but it tends to get a bit more expensive some where above 1 1/4 inch.

Just remember to have the outer end pointed down by at least 45 degrees to keep water out.

The problem with the antenna/rig combination you suggest is that first, the
ATAS 100 is a small diameter antenna even though it's apparently based on Don
Johnson's screwdriver, and the small diameter means that on 40 meters down, its
performance will be well down compared to more "normal" sized screwdrivers or a
bugcatcher. I personally don't think an Accord looks bad with a regular sized
screwdriver, but then again, I have call letter plates already too.

Easy Money for just one $10.00 bill and one stamp !!!!$$$$
WHAT HAVE YOU GOT TO LOSE???

BY READING THIS YOU COULD CHANGE YOUR ENTIRE LIFE FOREVER!!!
[now you will find US $10.00 bills in your mailbox !!!!! (NOT JUST 1$ BILLS)

! $31,250.00 in 4 weeks!!!!!!!!!

I found this on a bulletin board and decided to try it. A little while back,
I was browsing through newsgroups and came across an article similar to this
that said: you could make thousands of dollars within weeks with only an
initial investment of one $10.00 bill!!!!
So I thought, "Yeah right, this must be a scam", but Like most of us,
I was curious, so I kept reading. Anyway, it said that you send only
one US $10.00 bill to the first address in the list below
You then place your name and address in the bottom of the list at #3,
and post the article in at least 200 newsgroups. (There are thousands)
No catch, that was it.
So after thinking it over, and talking to a few people first, I thought
about trying it. I figured: "what have I got to lose except only
one stamp (not six) and only one $10.00 bill (us fund), right?"
Then I invested the measly $10.00 .

Well !!.GUESS WHAT.. within 7 days, I started getting money in the mail!
I was shocked! I figured it would end soon, but the money just kept
coming in. In my first week, I made about $250.00. By the end of the second
week I had made a total of over $1,000.00! In the third week I had over
$10,000.00 and it's still growing.
It's certainly worth a $10.00 used bill, and only one stamp,
I have spent more than that on the lottery!!

Let me tell you how this works and most importantly, why it works...
Also, make sure you PRINT a copy of this article NOW, so you can get the
information off of it as you need it. I promise you that if you follow the
directions exactly, that you will start making more money that you thought
possible by doing something so easy!

Suggestion: Read this entire message carefully!
(print it out or download it to your hard disk.)
Follow the simple directions and watch the money come in!
It's easy. It's legal. And, your investment is only one $10.00 US bill
(plus postage, only one stamp (not 6 , so the global cost will be a bit more
than 6 letters with $1 in each , but the amount of money you win
will be much more... and your wealth will be all made with thousands of
$10.00 bills ..... not $1 bills as other programs).

IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal;
and it is virtually no risk - it really works!!!
If all of the following instructions are adhered to, you will receive
extraordinary dividends.

PLEASE NOTE: Please follow these directions EXACTLY, and $30,000 or
more can be yours in 20 to 60 days. This program remains successful because
of the honesty and integrity of the participants.
Please continue its success by carefully adhering to the instructions.
You will now become part of the Mail Order business. In this business your
product is not solid and tangible, it's a service. You are in the business
of developing Mailing Lists. Many large corporations are happy to pay big
bucks for quality lists. However, the money made from the mailing lists
is secondary to the income which is made from people like you and me asking
to be included in that list.

Here are the 4 easy steps to success:
STEP 1: Get a piece of paper or a postcard and write the following on it
"PLEASE PUT ME ON YOUR MAILING LIST." , your name and address.
Now get one US $10.00 bill and place it into a dark paper(opaque)
so the bill will not be seen through the envelope (to prevent thievery) .
Next, place the paper or the postcard and the dark paper with the $10.00
bill
in it into the envelope and seal it (please seal it very well).
What you are doing is creating a service.
This is absolutely legal. You are requesting a legitimate service and you
are paying for it! Like most of us I was a little skeptical and a little
worried about the legal aspects of it all. So I checked it out with the U.S.
Post Office (1-800-725-2161) and they confirmed that it is indeed legal!
Mail the envelope to the first address in the list below:
(you send one $10 bill to the first name only)

1.)Oueslati abdellatif
B.P. 86/B , 3100 kairouan,
Tunisia

2.)David Camillier
B5-6900 crabapple drive
Whistler, B.C. V0N 1B6
Canada

3.)Jeffery Vincent
P.O. Box 46
Mittie, LA 70654

STEP 2: Now take the #1 name off the list that you see above, move the
other names up (3 becomes 2, 2 becomes 1,) and add YOUR name as
number 3 on the list.

STEP 3: Change anything you need to, but try to keep this article as close
to the original as possible. Now, post your amended article to at least 200
newsgroups. (I think there are close to 24,000 groups.) All you need is 200,
but remember, the more you post, the more money you make!

This is perfectly legal! If you have any doubts,
refer to Title 18 Sec. 1302 & 1241 of the Postal lottery laws.
Keep a copy of these steps for yourself and, whenever you need money,
you can use it again, and again.
PLEASE REMEMBER that this program remains successful because of the honesty
and integrity of the participants and by their carefully adhering to the
directions. Look at it this way, if you are of integrity, the program will
continue and the money that so many others have received will come your way,
too.

NOTE: You may want to retain every name and address sent to you, either on
a computer or hard copy and keep the notes people send you. This VERIFIES
that you are truly providing a service.
(Also, it might be a good idea to wrap the $10 bill in dark paper to reduce
the risk of mail theft. You can send a postcard with the dark paper and use
a thick envelope)

Your name will move up the list geometrically so that when your name
reaches the #1 position you will be receiving thousands of dollars
in CASH!!!

What an opportunity for only one $10.00 bill!

Send it now, add your own name to the list and you're in business!

---DIRECTIONS----FOR POSTING TO NEWSGROUPS------------------

STEP 1: You do not need to re-type this entire letter to do your own
posting. Simply put your cursor at the beginning of this letter and drag
your cursor to the bottom of this document, and select 'copy' from the edit
menu. This will copy the entire letter into the computer's memory. If you
are having trouble then start by clicking your cursor on the beginning of
this letter while continuing to hold down the click button of your cursor.
As you do this drag the cursor "all the way down to the bar" and past if
need be at the bottom of your viewing screen. Try it and you'll see .

STEP 2: Open a blank 'notepad' file and place your cursor at the top of
the blank page. From the 'edit' menu select 'PASTE'. This will paste a copy
of the letter into notepad so that you can add your name to the bottom of
the list and to change the the numbers of the list.

STEP 3: Save your new notepad file as a '.txt' file. If you want to do
your postings in different settings, you'll always have this file to go
back to.

STEP 4: Use multiple search engines like
www.dogpile.com/ or www.metafind.com/ to search for various usenet
newsgroups (on-line forums, message boards, chat sites, discussions).
If you are having trouble finding any then go on and try www.reference.com/
or www.liszt.com/ or www.forumone.com/ as examples to look in.
You may also wish to tell future readers from around the world that they can
read this letter in another language if they visit
http://babelfish.altavista.com/cgi-bin/translate or by going to

www.altavista.com/ and clicking on "AV Tools & Gadgets" and then click on
"AV Translation Service".

STEP 5: Visit these message boards and newsgroups and post this article as
a new message by highlighting the text of this letter and selecting 'PASTE'
from the edit menu. Fill in the Subject, this will be the header that
everyone sees as they scroll through the list of postings in a particular
group, click the post message button. You're done with
your first one! Congratulations... That is it! All you have to do is jump
to different newsgroups and post away. After you get the hang of it,
it will take about 30 seconds for each newsgroup!

** REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!!
BUT YOU HAVE TO POST A MINIMUM OF 200** That is it!
You will begin receiving money from around the world within days!
You may eventually want to rent a P.O. Box due to the large amount of
mail you will receive. If you wish to stay anonymous, you can invent a name
to use, as long as the postman will deliver it.
JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.

Now the WHY part:
.Out of 200 postings, every letter will be seen by hundreds of people but
say that only 5 will participate (a very low example).

So then your name will be posted :
by 5 people at the #3 position
(if every one sending 200 postings refers 5 persons)
your name will be posted by
(5*5) = 25 people at the #3 position
(25*5) = 125 people at the #2 position
(125*5) = 625 people at the #1 position

When your name reaches the first position in a few days, it will be your
turn to collect your $10.00 bills
Now you will receive mooooooooney!!!!!!!

and if just only 5 persons per 200 reply, your name will be out of the list
by
625 * 5 = 3125 persons and everyone will send to you a $10.00 bill,
so you will get

3125 envelopes * $10 = $31,250.00 !!!!!

(10 times more than other $1 programs with
the same number of letters in your mailbox).
AMAZING !!!!!!

$31,250.00!! With an investment of only $10.00!

**You may want to save this page to your hard drive for future use.
The More Times You Re-start THIS group, with your name added last
sending $ 10.00 to the first address and posting again
- everyone listed in THIS group is also started over.

This is why this program is better than others - it never stops!!!!

The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday? JUST LIKE YOU are now!!
So, can you afford a US $10.00 bill and see if it really works?? I think so...
People have said, "what if the plan is played out and no one sends you the money?
So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try? Anyway,
it is only $10.00 for a chance at thousands.
Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining the actual internet.
Remember, play FAIRLY and HONESTLY and this will really work.
You wouldn't want someone to cheat you the same way you may be cheating!
Yours sincerely,

Jeffery Vincent

Nah, N for no, C for credibility' or is it 'No Cordiality:

You have enough trouble with your own bs-cutting, such as describing '5 years' and now '2 posts', as 'many', to concern yourself overly with others. Adding to what Rick Littlefield wrote, 'Peek-a-boo, eyes on you. Deja tells a tale or two.'

Before your next sally into revisionist history, see:

http://www-tsc.upc.es/eef/research_lines/antennas/fractals/history.html

Another thing: stop your gratuitously insulting attempt to think for 'all'. Cede us the right that you would undoubtedly claim for yourself.

Just 'give it a try'.

Quoting from the ROHN catalog and engineering book...The figures for a properly installed self supporting 25 G are: 70 MPH wind survival and *NO* ice...At a 40 foot maximum for a 25 G the maximum allowable wind load is 1.5 sq. ft of antennas consisting of "round" tubing.

And why would using both at the same time be bad??
We do it all the time with repeaters.

If the 2-meter frequencies are at least 600 KHz apart, 4 cans will work, but
6 will give better isolation.

Unfortunately using cans willrequire that both radios be kept on a specific
frequency. In other owrds, only one packet frequency and only one FM
frequency.

Not to mention the skill required to tune up a set of bad pass/band reject
cavaties.

Roger, try to keep it in the context of the original message. I know that repeaters do it all the time, but as you say, 4 cans may be necessary. The gentleman was asking about a VHF-VHF duplexer. Are YOU saying that you could run one antenna with two rigs with a simple duplexer?

I have a modified 2 meter beam that was previos to last summers qst article converting a fm antenna to two meters. It has been gama bridge matched and is nearly right on at 1:1 in the center freq. When i have it 15 feet in air and aim it and steer awayat from repeaters i dont hear the directionality i like to see. Is it critical that the elements need to be of proper length?

> --
> http://www.mindspring.com/~w6rca

I gotta side with you on this one. I'm sure it's a good antenna as I've heard many favorable reports on it, but 10 dbd gain? The unwary would think it's equal to a full size 4 el yagi. I really doubt it's quite that good. My cushcraft A4 is only rated 8.9 db. "Not sure over what". But the A4 is a pretty good sized beam. Which do you think would win, the A4 or the hexbeam? I'm afraid I'd have to put my money on the A4, and it's a compromise tri bander to boot. One example of using anecdotal reports to state gain would be to compare my 40m ground plane to my dipole. I could work 200 miles away, and the dipole would be better. I could work 2000 miles away and the ground plane would be better. Does it have gain over the dipole? Of course not. The dipole has gain over the GP. It's just spraying it in different directions and angles. My GP would be 4 s units better to VK land. That would equate to about 6x4=24 db gain!!! NOT!!!!If I were to state my GP having 24 db gain over my dipole I would get laughed off the net. This is another reason I frown on stating antenna gain in any other way other than free space when advertising or even just stating antenna performance in general. I may say my GP is 4 s units better to a certain place at a certain time, but I would never equate that to a given db gain as far as the antenna. Also I'm sure he has really seen 10 db over the dipole he compares to, so I'm not saying he's fibbing, but again that doesn't always mean the antenna really has that much gain. There could be other factors involved. Sorry folks, but to me it is a little snake oilish. I've tried optimizing full sized 2 el yagis and never got that much gain. And lucky to do better

than 10 db f/b. And thats a full size antenna. Heck, a full size 3 el NBS yagi, only does about 9.5 DBI or 7.4 DBD, with a appx 10.5 db f/b ratio. Will the hexbeam beat a full size 3 el yagi? I'll be eagerly awaiting replies...MK

Are you not using a PUBLIC forum as well? Why does my disagreeing with you in a PUBLIC forum have anything to do with business?

From another perspective, why is it acceptable for you to publicly state your technical and non-technical opinions but when I state mine, you conclude that I must have ulterior motives? It is ethically and morally acceptable for me to disagree with you and state that agreement in response to your public posts on this newsgroup. The real issue for you is that you find it untenable that anyone disagrees with you publicly. When my disagreemts have been stated, your only defense of your position has been claims that I don't understand basic concepts or that I am out to get you. I am not out to get you, I disagree with some of your technical comments. Its really that simple.

Absolutely agreed; I can imagine no antenna where the radiating near field would would extend even a tiny fraction of a mile. If the reactive near field is varying as 1/D^2 and the radiating field is varying as 1/D, even though the reactive component of the field is >> the radiating component, it does not take a mile for the reactive field to decay to < the radiating.

> which direct and reflected waves come together to produce a radiation
> pattern. That definition is completely alien to me.

The ARRL Antenna Book discusses the differences between the reactive near field (the one you discussed in your post) and the radiating near field. The former is pretty well defined; the latter is more a convention. The term radiating near field has meaning when a point being evaluated is physically near an antenna such that it is not approximately equidistant from all parts of the antenna, as one would be in the extreme far field. At this point, the E and H fields may not be at right angles, may have an E/H ratio of 377 ohms and may not vary as 1/D. In this region, it is entirely possible for one field to be varying such that it actually increases with incresing distance from the antenna. The reason I call it a convention is because this is the phenomenon that both you and characterized as being related to just how close one feels one needs to be to far field to be able to make use of the calculated or measured results.

One of the reasons that I keep bringing ground into near-field/far-field conversations is that when one is near the ground, the ground also exhibits near-field phenomena. On a perfectly conducting plane, the E field is zero, for example. That, coupled with the fact that one must be very far away from an antenna that exhibits a ground reflection in order to see the far-field pattenr predicted by programs like NEC, indicates that ground is indeed an integral part of the performance of most antenna systems, in sundry ways, each of which may need to be considered when considering the performance of a specific antenna.

There is no current in a virtual antenna below the ground; the performance of an antenna over ground is as if there were a virtual antenna. It is sort of like how gravity and acceleration both produce the same effect. Shine a light at a mirror. The result is 100% a reflection phenomenon, but the effect appears for all practical purposes as if there were a second light located behind the mirror, at a distance from the mirror exactly equal to the distance from the real light to the virtual light.

Terman is completely correct; there is little mutual coupling between an antenna and ground when the antenna is at significant heights. The effect of ground reflection is no more affected by mutual coupling than is the light from the flashlight affected by the reflection. Trying to say that the reflection does not exist because there is no mutual coupling between the flashlight and the mirror is incorrect.

One would be equally hard pressed to detect any reactive energy at D=3.18a^2/lambda. The reactive near field decreases very rapidly with distance. The formula you cited gives approximately the same answer as NF=2D^2/lambda and both are estimating the distance of the radiating near field. (Discussed in another post this AM.)

2069. Re: Rhombic antenna for 10m

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-10 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A0C1176.A9637C84@eznec.com>
Source record: 176733

The "virtual" or "image" antenna is a conceptual aid which might actually create more confusion than enlightenment. Its current doesn't arise due to any effect akin to mutual coupling, but is purely fictional. Consider the ray emanating from an antenna placed over perfect ground, striking the ground, and reflecting from it. Now remove the ground and add to the model an "image" antenna which is identical to the real antenna and driven with the same magnitude current but out of phase with the real antenna. (Remember, this current doesn't come from mutual coupling with the real antenna, but is supplied as necessary to make the model work. Both the antenna and its current spring from our imagination.) The "image" antenna location is directly below the real one, spaced twice the real antenna's original distance from the ground. With a bit of reflection (pun intended) you'll see that the field from the image antenna is exactly the same as the one which was produced by the reflection of the real antenna's field from the ground. The sum of the fields from the real and image antennas is exactly the same as the sum of the direct field rays from the real antenna and the rays reflecting from the perfect ground of the original model. So the pattern is exactly the same for either model. We've simply substituted the image antenna for the ground and gotten the same result. When the ground isn't perfect, this substitution is still reasonably accurate for horizontally polarized waves, but the accuracy degrades at higher angles because the quality of a real antenna's reflection deteriorates at those angles.

Now, it turns out that you can also account for mutual coupling with the "image" concept. Note the feedpoint impedance of the real antenna when placed over perfect ground. Remove the ground and substitute the image antenna as before. Calculate the feedpoint impedance of the real antenna as modified by mutual coupling to the image antenna. You'll find that the feedpoint impedance of the real antenna is the same as it was over real ground. But again, the image antenna doesn't depend on mutual coupling for its current; we impose its current. After all, we conjured the image antenna, so we can conjure its current just as handily.

These phenomena can be easily shown with the EZNEC demo program. (I apologize if my frequent mentioning of this is getting tiresome. But I really feel that it's very useful in illustrating many of the concepts mentioned in this newsgroup. Nearly any other modeling program will do as well, but one good feature of the EZNEC demo is that it's free.)

Richard Harrison wrote:
>
[snip]
>
> But, the energy from an antenna 180 wavelengths above ground is spread
> far and wide before it reaches the ground.

That doesn't matter. The energy is either reflected, or absorbed. The context of this thread has been that the reflection is near perfect specular (mirror like) at near grazing angles. The assumption of perfect specular reflection can be significantly in error due to ground absorption and surface roughness except at near grazing angles. As long as the reflection is specular, it doesn't matter that the rays are 'spread far and wide'.

Take out a piece of paper and draw a horizontal line corresponding to the reflection plane. Now draw an isotropic point source somewhere above the plane and trace a few rays remembering that parallel rays appear to come from a point source when viewed from somewhere in the far field region. Include a few reflected rays.

Now take out a colored pencil and draw another point source located symmetrically below the reflection plane and trace out a few rays _ignoring_ the reflection plane. In other words, a ray coming from below just keeps going straight when it encounters the boundary. You will see that the rays coming from the 'image' source below the reflecting plane are indistinguishable from those reflected from above. Geometrical spreading is not an issue.

> There is nothing to focus the
> energy on the ground space directly under the antenna, and the energy
> certainly is not columnated as is laser light.

Each 'ray' leaving the antenna may be considered collimated. As long as it doesn't lose it's collimation, which is a common working definition of specular reflection, it doesn't need refocusing.

> The volts per meter and
> the watts per square meter are greatly reduced at ground level.

That's correct, the energy density is low but there's a large area involved. If it isn't absorbed, it must be reflected.

> Remember that the image antenna should behave exactly as an actual
> antenna would in the virtual position were that perfect ground removed
> and replaced with a real parasitic antenna.

The image antenna abstraction requires the image antenna be excited with a particular current and phase. The current and phase are chosen in order to achieve the boundary conditions which would be imposed by the ground.

For example, if the ground is perfectly reflecting, then ohms law requires the tangential electric field at the ground surface be zero. The image model is derived from the fact that it is possible to chose an 'image' location such that if it's fed with the correct current and phase, the summation of the fields of the real, and image antenna are consistent with the boundary condition enforced by the laws of physics. It turns out that in the particular case of the perfectly conducting planar ground, the image antenna is located symmetrically with respect to the 'real' antenna and ground plane, hence the term 'image'. The excitation of the image is required to be of opposite phase and identical current as the real antenna in order for the fields to be consistent with the boundary conditions imposed by the ground. e.g. the electric field parallel to the ground will vanish at the boundary.

The image antenna is not in any way assumed to be parasitically excited.

> Scratch the parasitic if the
> antenna is driven against ground.

The image antenna necessarily has the same current distribution as the 'real' antenna. Since the image is a mathematical convenience and does not truly exist, there is no concern about how it may be fed. It is simply assigned a current distribution identical the the real antenna.

> Why is a Yagi reflector placed 0.1 to 0.3 wavelength behind the driven
> element? Would it receive the same excitation at a distance of 180
> wavelengths? You know the answers.

The so called 'reflection' which occurs in Yagi antennas is something of a misnomer and in my opinion, has very little to do with the topic of this thread.

> Radiation from the image of a dipole 180 wavelengths above earth doesn`t
> begin to equal the radiation from the elevated dipole. No violation of
> energy conservation rules are in volved. Only geometrical spreading is
> involved.

The current distribution is identical to that of the elevated dipole. Therefore at distances very far away from the antenna system, the fields must be identical except for the phase which is dependent on the horizon and azimuth angle. The far field pattern is the product of the radiation pattern of a single element multiplied by the term arising from the geometrically dependent phase term.

> I`ll give you a microwave example.

> along the microwave path. Very large dishes were often needed to focus
> the microwaves so that the first Fresnel zone of energy would all hit
> the reflector. Without the focus of energy on the reflector most of the
> energy would be wasted in useless directions.

A less economical alternative is to increase the size of the reflector
so that _all_ (or nearly all) the fresnel zones are reflected. Then the
far field pattern is identical to that of the dish located at the
reflector location. This is the case which more closely matches the
ground reflection scenario being discussed. The case you are referring
to has the reflector in the near field of the antenna, has many
advantages such as a few extra dB of gain and shorter waveguide runs but
I think out of scope here. Would be an excellent and informative topic
for another thread.

Then you should only expect the same and quit complaining.

From what I've seen here - you are being treated "...with exactly the
measure of respect that your given post warranted".

Only modification I'd add is you have MANY 'given posts'

You will be treated thusly until you change. Which is about as likely as
Nader making into the Whitehouse - or a straight answer from the
"Fracloud".

Hope that helps

What Rick posted is entirely correct for all medical practitioners, not just shrinks, whether you want to accept that reality or not.

An orthodox or observant jews does not "work" on shabbos. And that means, no electricity, no cars, no telephones, etc. You can't turn it on during shabbos.

Now some get around that by leaving things on (always on DSL is good for this because no phone call is necessary), but then I guess your would not be too observant then.

Remember, you don't know the time zone of where the poster is and shabbos ends based on local sunset times plus an offset.

The only way such information could be made public or used in a court of
law would be if you were the subject of a sanity hearing. Which, given
past performance, is a real possibility in my opinion.

The bottom line is you have (again) set up an impossible challenge.

The article on the 6-meter modification was published in QST Hints &
Kinks, December 1974. It was probably in one or more of the Hints &
Kinks books published after that, but I don't have any of them now.
Hope this helps. Perhaps your local library has back issues of QST.

SPACE WEATHER BULLETIN #00- 11
2000 November 09 at 12:20 a.m. MST (2000 November 09 0720 UT)

**** SEVERE SOLAR RADIATION STORM ****

A severe solar radiation storm began today, 8 November, at 4:50 p.m. MST (2350 UT), and has reached a level of S4 on the NOAA Space Weather Scales. The storm, which currently ranks as the fourth largest since 1976, is expected to peak over the course of the next several hours and then slowly diminish over the next three to four days.

This severe radiation storm could pose a hazard to the astronauts on the International Space Station as well as passengers on commercial airlines flying at high latitudes. The storm could also adversely effect the operation of satellites.

On Thu, 09 Nov 2000 12:17:46 -0800, Roy Lewallen <w7el@eznec.com> wrote:

This comment isn't in response to Roy's remarks, this is just a handy place to jump back into this thread.

I earlier stated that in the model of a dipole above ground, the null depth was not dependent on height above ground. This is incorrect.

As Senator Blotto would say, I would like to revise and extend my remarks.

I did some more fiddling around with a dipole resonant (zero reactance) at a wavelength of one meter. I placed this antenna at various heights above a perfect ground and determined the depth of the null at 90 degree elevation.

I started at 1/2 wavelength above ground and increased the height by a factor of 2^n where n is an integer. Some of the data follow:

Height (lambda) Null Depth (dB)
0.5 -82.14
1 -76.1
2 -70.1
4 -64.07
8 -58.06
16 -52.03
32 -46.01
64 -39.99
128 -33.97
256 -27.95
512 -21.94
1024 -15.95
2048 -10.04
4096 -4.47

For the above numbers, the null depth is approximated (within 0.05 dB) by the function:

dB ~ 20 * log(lambda) - 76.11

up to about 1000 lambda. The reader is invited to extrapolate to greater heights.

Using two freespace dipoles separated by twice the height and fed equal power but 180 degrees out of phase gives exactly the same results.

I'll let this stand without making any more foolish comments.

Nope, as posted by Rick, it would take a court order to get a reputable
practitioner to release any patient records, at least in the US, don't
know about other countries.

Next time you're at the doctor's try asking for an x-ray so you can have
a print made to hang on your wall. Most doctors won't even do that, let
alone release detailed information.

Ed G. wrote:
"What was decided (in layman`s terms) on the rhombic?"

I think some of us agree the definition of the dividing line between near and far fields is a limiting distance beyond which the reactive energy which returns to the antenna is inconsequential. Just how far away from the antenna that is can depend on the user`s needs. But Terman and many other authorities say a good choice may be about 7 wavelengths from the dipole antenna.

The term "near field" may have been used to define a reflection zone by some. I have never seen that, but I`ve never seen a computer antenna program or any of the new ARRL antenna books either.

I have watched Collins Radio measure the characteristics of a log periodic antenna about 40 years ago at their Richardson, Texas plant. The antenna and sensor were mounted at rather modest heights outdoors over the ground. The antenna mounting allowed them to rotate, turn 90 degrees on its axis, or tilt the tested antenna. It may not have given true free space results. Collins may have only wanted the results of a log periodic mounted at that particular altitude. I`d wager that the results obtained were good enough for comparison and practical purposes. They obviously had rather elaborate test facilities with automatic pattern print outs, etc. The radiation sensor was obviously not miles away, but it was a number of wavelengths away. I`d further wager that the results were reasonably representative of the free space directivity of the log periodic which was no where near 180 wavelengths above ground.

This discussion could go on forever and we might learn from it . I am tired of it myself.

Best regards, Richard Harrison, KB5WZI

At least in Oregon, any patient can get a full copy of his or her medical records at any time. What the patient does with that copy is up to the patient. No one else can get a copy without a court order or written permission from the patient.

I do not know of any antenna type where the reactive near field would be 7 wavelengths away from the antenna. I think you are still inter-relating the reactive near field with the radiating near field. The former is one of reactive energy being returned to the antenna -- the latter is one of radiated energy, but in a location where one is not equidistant from all parts of the antenna. This can occur very far away from the antenna for physically large antennas.

> The term "near field" may have been used to define a reflection zone by
> some. I have never seen that, but I`ve never seen a computer antenna

The term "near field" is not used to define a reflection zone. What I offered is that to make a far field measurement in the presence of a ground reflection, one must be far enough from the antenna that the size of the system, including the ground reflection, is in the far field.

FRacky- I, for one, do not expect, nor need, a report from a mental specialist that has examined you professionally- The fact that you place yourself in a position of getting help would be enough.
Believe it or not, there are many of us out here with some experience (from the inside, or the outside) with mental problems. Some of us are convinced that you have a problem. Most of us merely want you to get help. This is not a retribution problem, but a sincere desire to help you.

Your last paragraph (below) is an illustration of some of the symptoms that indicate that there is a problem.

Hope this helps. Bill-W4BSG

Hard to say for sure, but if you are pretty clear in the distance you
should do pretty well. With a 3 el I have at about 35 ft I can talk all
the way across town with 5 watts. A good 30 miles I would say. "Thats
with a equal antenna on the other end". The others guys setup will share
50% of the range capabilty. You might only work 5-10 miles to a guy with
a ht standing in the yard. You might work 70 miles to a guy with stacked
yagis at 90 ft. All depends. But I can assure you, you will do ok,
unless you are trying to work 170 miles away or something. With my
present 50 watt rig and only a 3 el, vertically polarized, I'm fairly
loud in most areas of Houston which is a big area. And actually I rarely
run 50w. I'm usually only about 28 watts on simplex. MK

> >

How long is the dipole? I'm not familiar with the JR version. The normal G5RV is 102 ft long. If it's working good, You may not need to do anything. Myself, if I were doing that same thing, I would feed a 40 meter dipole with 450 ohm ladder line all the way from the tuner to the antenna. I wouldn't use any coax sections, or chokes etc. I'm not sure if yours has all that, but if it does, it may possibly improve it a bit to run ladder line the whole way. If it didn't, you could always switch back. When using a single dipole for multi band use, I usually want a full half wave dipole for the lowest band. But like I said, if it aint broke, you may not need to fix it. Also always try to use the minumum inductance to tune. That will lower tuner losses. MK

2096. 6 meter beam

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-10 00:00:00 UTC
From: "Ed Hare, W1RFI" <w1rfi@arrl.net>
Message-ID: <CQ_O5.78$g5.334471@news.ntplx.net>
Source record: 176760

Unfortunately, I accidentally deleted a post from a fellow looking for a 6 M beam that had a good SWR across the band. I used Antenna Optimizer and came up with the following. The dimensions are for just the elements, no boom, but they can be corrected for the presence of a boom using the usual correction factors (ARRL Antenna Book, other sources). Being lazy, I won't do all the math to translate the variables that AO calculated into the acutal dimensions, but I trust the format of the AO .ant file is reasonably self explanatory.

```
3-Element Yagi
Over Ground
52.000 MHz
3 wires, feet
seg = 7
height = 10.5
dia = .625
f = 52
refl = 239.4162
del = 213.2212
dirr = 158.2793
ref = refl/f
de=del/f
dir=dirr/f
front = 4.18
middle = 0
back = -4.18
seg back -ref height back ref height dia
seg middle -de height middle de height dia
seg front -dir height front dir height dia
1 source
Wire 2, center
```

The lines that start with "seg" are the antenna element lines. They are formatted as follows:

```
end 1 end 2 conductor diameter
#segments X Y Z X Y Z diameter
```

where #segments is the number of segments I used in the program calculations, X, Y and Z are the coordinates for the ends of each wire used.

The performance of the antenna is:

```
+----------------------------------------+
�Freq�50.000�51.000�51.000�53.000�54.000�MHz�
+----+------+------+------+------+------+---�
```

```
�Gain� 10.28� 10.41� 10.41� 10.68� 10.82�dBi�
�F/B � 15.99� 16.60� 16.60� 14.19� 12.90� dB�
�Zr � 43.6� 47.4� 47.4� 56.5� 60.6� _�
�Zi � -8.76� -2.02� -2.02� 14.41� 23.2� _�
�SWR � 1.29� 1.11� 1.11� 1.32� 1.55� �
+----+------+------+------+------+------+---�
�Gain� 10.29� 10.42� 10.42� 10.69� 10.82�dBi�
�F/B � 16.03� 16.56� 16.56� 14.18� 12.89� dB�
�Zr � 43.8� 49.1� 49.1� 56.7� 60.9� _�
�Zi � -8.17� -0.26� -0.26� 15.15� 24.0� _�
�SWR � 1.27� 1.06� 1.06� 1.34� 1.57� �
+----------------------------------------+
�Variable� Value� ☐_
� refl� 239.4162� 0_
� del� 213.2212� 0_
� dirr� 158.2793� 0_
```

This was just a quick calculation -- I could have probably played more with element spacing, or not worried about having a 50 ohm feed point. AO is MININEC based, so may not be as accurate as NEC-based models. What I have done for other antenas I have optimized is first us AO to optimize, then re-enter the program into EZNEC, find out what it really does, then make minor tweaks in EZNEC to get it right. If my explanation of the AO file left anything to be desired, email me this weekend at w1rfi@aol.com. For now, I still have my AOL account. :-)

2097. Re: Beam Antenna Bandwidth

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-10 00:00:00 UTC
From: "Dr. Robert Suding" <robert@qadas.com>
Message-ID: <3A0C80FC.7C9FA485@qadas.com>
Source record: 176761

I generally figure on a 3 element beam that the director would be 5% shorter and the Reflector 5% longer than the driven element. To get greater bandwidth, you could make the directer even shorter, maybe as much as 8% and the reflector longer by 8%.

Another trick would be to use thicker elements or even a bow tie radiator.

In today's software ham world, I would model the different options on AO, EZNEC, or NEC WIN + and select the one that best fits your parameters. Less than a few hours would save days of cutting & drilling!

From: CW <cmagers@sprynet.com>
Message-ID: <8uidsakaa1@slb7.atl.mindspring.net>
Source record: 176764

I use nothing but coax. Reason being, interference from household appliance, wiring ect. I have never used balanced line but from experience with a random wire fed right from the tuner it would seem that noise would be a problem. I have heard the bit about turning off everything in the house that causes problems but that is not very practical for most people. With the apparent popularity of balanced line, I'm wondering how you solve this problem.

Message-ID: <rd4P5.374$9U1.17146@news.inreach.com>
Source record: 176765

CW:

Theoretically, the noise pick-up of ladder line should be minimal because the currents induced in the feed line by noise sources will be common mode, whereas the signals coming in from the antenna will be differential mode. Your tuner should respond only to the differential mode signals while the common mode signals cancel out. The reality of the situation will never reach the theoretical, of course, but the noise pick up should not be a problem...

Ed Hare, W1RFI wrote:
"Yes, but the reflection still takes place."

Agreed. On a microwave path there is only one reflection point. We say the direct and reflected waves have traveled almost exactly the same distance so they can be expected to have nearly the same strength should there be an efficient reflection. So, there could be as much as a 6 db gain over the direct ray by itself, to complete cancellation if the two rays are completely out of phase.

We have concentric Fresnel zones surrounding the straight line between antennas at the path ends. The odd numbered zones are good news and the even numbered zones are bad news. In engineering the path we try to stay within the first Fresnel zone by our path clearance choice. We usually shoot for 0.6 of the first Fresnel zone clearance. We also try to choose a non-reflective spot for the path to graze. We avoid water when we can. That is very tough over the ocean, of course.

Best regards, Richard Harrison, KB5WZI

"The effect of a reflection off of perfect ground is exactly the same as the effect of feeding another antenna, located 2H below the first antenna in free space, where H is the height of the antenna over perfect ground."

It is hard for me to see how you get enough current in that virtual image antenna for big radiation from it when it is very far away.

Terman has Table 1 in his chapter on antennas and it shows the resistive component of mutual impedance between two parallel half-wave-length radiators. Values run from 73 ohms at zero spacing down to 0.06 ohms at 7 wavelengths spacing. There was no use to extend the table to greater spacing as 0.06 ohms is already insignificant for most purposes.

I this case it is using ABS for a mast which should not affect the
directionality. Now, I think using a fielf strenght meter will work. I
did cut the elements slightly short but made up with it by sticking
smaller tubing in the ends and put the cut pieces on those smaller
ended so its adjustable. With a 5 element beam 460 feet up on a hill 20
feet above the ground at 5 watts what kind of distance should I get?
nothing is obstructing it in front of it but a small cheary tree on the
right and a pine tree 20 feet higher then it is on the left with both
spaced 25-30 feet and antena in between.

Source record: 176808

What happend to your question on front to side ratio?

Now you are asking how much distance should you get.
That's a "bag of snakes" question!
There is no single answer to that question. Perhaps a good
rule of thumb on 2M FM is "line of sight plus" meaning you
should be able to work anything your antenna can "see" plus
some stuff your antenna can't "see". I have a 5 element beam
and worked a station on 2M sideband 97 miles away today, cross
polarized. But I have trouble hitting a repeater on FM 30 miles
away with both antennas vertically polarized, due to
topography between antennas.

In addition - you did not state the gain of the antenna - is it
optomized for gain or F/B, how long is the feed line and what is its
loss, what is its polarization, are you still talking FM or is it SSB,
what is the antenna at the receiving site, how high is it, what
is its polarization etc etc etc - there are a LOT of factors that come
into the "how much distance should I get" question.

hey pete
congrats on the new radio
i would suggest a 5 ele yagi for 6ssb which is where the most of the activity on 6 is but keep in mind it is NOT like 10 or 20 meters 6 doesnt open all that often you spend a great amount of time monitoring and listening to white noise but when it does open its great fun
as for HF your on your own

2115. ICOM AH-4 antenna tuner question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-10 05:43:26 UTC
From: Phil <philvdk@pandora.be>
Message-ID: <2WLO5.100041$il2.2121180@afrodite.telenet-ops.be>
Source record: 176811

Hello,

A bought a IC-706KIIG a few weeks ago. Because I'm very limited and restricted to put up antennas, I've ordered a AH-4 tuner to go with my IC-706. My situations is as follows :
Living on the first floor, I have a balcony (metal and extends via neigbours) that I want to use as counterpoids. I want to put up a wire (21 feet) as a slooper attached to a three.

Some questions :

- Would a vertical solution work better
- If so, can I wound a wire around a fiber stick to gain antenna lenght ?
- When I use the slooper, can I also use a wounded wire around plastic pipe to gain antenna lenght ?
- When I wind wire, will it go with the tuner or can I only use this for single band antennas ?

All info or tips regarding my restricted situation is welcome !
Tks and 73 de Phil

If you have a addic you can put up some radials under the roof and use them
as RF ground ...
The more you put up, the better the antenna wil perform

Ed Hare, W1RFI wrote:
"One cannot measure the actual gain at any elevation without including the ground reflection and one must be in the far field to do it."

I quoted Griffith earlier in this thread. He said that there is an induction field in the immediate vicinity of an antenna. This induction field consists of lines of force set up by voltage and current in the antenna and these collapse back into the antenna twice each cycle. The inductive field contains only reactive energy. These reactive electric and magnetic fields are 90 degrees out of phase with each other.

Strength of the inductive field intensity is approximately proportional to the inverse square of the distance.

The radiation field consists of lines of force which have become detached from the antenna and are moving on out into space as an electromagnetic wave. It consists of real power and diminishes much less rapidly than does the induction field. This intensity is inversely proportional to the distance from the antenna.

At 1/2pi wavelength, the intensities of the induction and radiation fields are equal. Closer to the antenna, the induction field is the stronger of the two. At greater distances, the radiation field predominates.

It is common to choose 1 mile as the distance to start specifying the field intensity of an antenna. For all but the longest wavelengths used in radio, 1 mile is far enough o be well outside the induction field region, but close enough for measurements.

I mile is well outside the near field (induction field region) at 1 MHz, or a wavelength of 300 meters. 300 meters is about 1/5 mile, so a mile is about 5 wavelengths.

Terman and Griffith agree. Terman says the induction magnetic field is inversely proportional to the square of the distance and the induction electric field has a component that is inversely proportional to the cube of the distance. Terman is using volts and amps, not watts and vars. In my earlier posting I quoted per square meter values and said they were the square of the per meter values. These squared values decline as the 4th power of the distance for the induction magnetic field, and as the 6th power for a component of the induction electric field. The radiation field declines as the 2nd power or square of the distance from the antenna, and this can be easily measured outside the near field.

The point is that the near field which contains significant amounts of reactive components doesn`t extend very far for practical purposes.

It now appears to me that Ed is using the classic "near field" term to mean something entirely different from a region containing significant quantities of reactive energy. He seems to be defining it as a region in which direct and reflected waves come together to produce a radiation pattern. That definition is completely alien to me.

Best regards, Richard Harrison, KB5WZI

Thomas Edison describes in his patent application for the wireless telegraph in May of 1885 as follows;
For receiving signals I locate in said circuit between condensing surface and the ground a diaphragm sounder which is preferably one of my electro motograph telephone receivers.

The first wireless telegraph picked up the telegraph signals with a loud speaking telephone. De Forest patented his triode in 1907 twenty two years later. For his first radio he used an Edison loud speaking telephone.

Edison's Patent and an essay about wireless transmission can be seen on my site at www.geocities.com/starapex Click on the radio

By Golly, I thought the sentence to use the tapes "To learn electronic theory" would have made it clear that the intended use of the material was for electronic theory only which really hasn't changed that much. The question pools are irrelevant as the tape are for use in Canada and we have our own question bank.

I was trying to be as clear as possible without tying-up a whole lot of bandwidth.

BTW the tapes are for someone with a type of polio virus who cannot attend regular classes.

If you hear of any lying around, please let me know.

thanks

Message-ID: <20001111091900.01637.00000062@ng-ck1.aol.com>
Source record: 176680

I'm trying to find out people's experiences with a 40 m single quad loop mounted close to the ground. For example, the bottom wire about 8-10 ft from the ground, either a square or diamond configuration. I'm particularly interested in experiences with comparisons to a vertical antenna that has a good ground system (e.g. 10-20 radials). My biggest interest is stateside coverage, can't seem to get QSL cards from foreign hams, hi.

Thanks for reading the posting.

73s,

Evan

Source record: 176681

Evan, you'll probably get numerous opinions. Assuming you refer to vertical polarization, the loop will out perform the mono-pole vertical given the same far field ground condition. Primarily because it is bi-directional since the actual TOA (take-off) angle will be the same for nearly all verticals; ie far field ground. And because of the directional characteristics and the closed loop, some improvement in signal to noise will be gained From the loop.. Near field ground radials are not required although it is argue over very poor near field ground radials may also improve the loops performance--absolutely required for the monopole. I have run both (generally in arrays) for years and the 40meter loop does well and can also be an excellent multi-band antenna if fed properly.
You may also want to note, a dual 40 meter array loop (beam) can be errected using one support and take up little room while really providing outstanding performace.....I suggest you get a copy of "Low Band Dxing" at any local Ham store. gd. luck and 73 Bill (k6ec)

Cam:

I like the Gates effect answer...

But whatever device feeds the ladder line in differential mode (tuner or balun) should have pretty good rejection of common mode signals, except of course for the unavoidable capacitive coupling.

Wasn't my idea, it's done all the time in these parts, it's almost expected. We have a body shop which will do the whole nine yards for $200. Cobble together a steel mounting bracket which gets welded to the chassis, undercoat it and paint the HF antenna to match the car. For another $50 he'll pull the headliner down and punch the hole and install the vhf antenna.

Looks like a good compromise between a real bugcatcher and a Hamstick. A lot less windload than a bugcatcher for certain. Gets down to the losses associated with 1.5" vs. 3" diameter coils.
>
I'm still harboring illusions about using a roof-mounted version of a Saint Looie Special 20ft vertical for fixed-location mobiling. The problem is the mag mount. The monster Hamstick mounts would be fine except that the things suck up too much storage space in a small trunk like mine. I could easily build a knock-down or folding mount but I can't find the big magnets like Hamstick uses. Edmund and McMaster-Carr don't have 'em. Any suggestions??

Evan, I don't understand what ypu mean by single quad loop. So, I'll answer you the best way I can. For years I ran two three element 40 meter quads nested so that they were at right angles to each other around a common center-axis. I suspended them on cantenary lines in the middle of a 4 element phased vertical array on for 80 meters.

By making either outer loop with a small, about six foot section off 6 inch steatite spaced ladder line, and the primary dimension of either outer loop about 5% short, I could simply cut the ladder line on either side in or out of the circuit with a switch and reverse the throw of either of the two quads. More interesting, I could actually even use a coaxical power divider network, and split the power between both quads, thus driving the pattern up the middle between any two. It made a neat and fully operational way to make an eight lobe pattern, as opposed to just the four-way throw one would normally expect from such an array.

My K6STI pattern log file is full of studies I did on this one. It turned out that Brian's predictions as to what I could expect are about right on the money in practice.

Your describe attempt make this antenna, for close-in work, as a relatively high-angle device, are right on target. It is, but with one caveate! We'll get to that in a moment. Let's see how it worked out in practice - I only work single band contest stuff, I'm not good enough to be big cheese in multiband efforts, OK?

Back in about 1965, as far as I know, it ain't officially record-kept stats, it was published in QST that I'd broken the single band total QSO and score known, unofficially on 40CW. But that was not with this quad deal! The ARRL checker made the wry comment in the stats, that, "Maybe he should go back to Texas!"

I *FINALLY*, after some 35 years of trying later, roke my own totals, with this device and .. once .. I've collected the clean sweep cup on a solo 40CW entry with it! But it *NEVER* did well enough, I thought, for the work to fool with it and keep it all going, on DX. You must remember, for purposes of comparison here, that I am in Central Texas, not quite, but almost on the line of the most barren sand soil conductivty short of the Sahara Desert. A wet noodle in W1 or W6 land will have a 20 DB better basic signal to work with that I ever get from any but a South throw.

Every now and then, a pig stumbles on a acorn!

On day I stumbled on a KL7 using a single 80 meter loop just like you suggest? He told me it was worthless on 80 until he fed it in vertical polarization mode! Thwpttt, out came the the modeling program .. and .. I saw immediately he was right! There was a projected and a practical reduction in vertical takeoff angle of these loops, the intant I started feeding them in the corner, so that one element of the dipole was going, more or less, straight up from each feed point!

Again, this is Central Texas, remember? My 40CW total country count in the CQ WW went from about 85 countries a contest, to about 90-92, and the zone count picked up one or two in the deep Asian game from that work. Brian's modeling also told me something else about doing this on low band work with these loops. It told me that more than three elements was worthless. The reason is that the ground image grunges up the whole deal close in to the ground for more than three quad element loops, telling it as a practical answer to what happened. I'll leave it to those far better than I do tear that apart and fractionate the discussion beyond that.

GDRFC!

Incidentally, all these were SHUNT FED loops! Coax tied right to the loop and fed from a gamma match about six feet long from those same six inch steatite open wire feeder spreader formed sections. Works wonderful, and so easy to tune it's silly.

Then. One day I got mad at all the work and put up a single elevated vertical, just to see how it would do is CQ WW.

Pow .. about 90 coutries! This is like comparing not eating pork to having fun with the opposite sex! Darn site better, just between us Pious and Holy folk in this echo!

So .. I extended that single 9 foot high elevated shunt fed all grounded vertical into a full four element elevated phased vertical array. It has only four radials per pole, totally shunt fed and solid grounded. Surprise, I popped 100 countries worked in the CW WW and/or the ARRL DX contest on 40 only that year..

Down came the wire quads.

Wistfully, I think that before I took them down, I should have made one more run at something. I should have rotated the feed point from the corner down at the bottom off that lower wire loop -- up to the middle of the vertical wire element segments. It really wasn't fair to the study not to do that, so as to get all of the vertical component into the maximum current segment of the loop. I *THINK*, had I done that, I might not have seen much difference between it and the vertical four square. In fact, I suspect had I done that, the antenna might be a little quieter and have a bit more gain.

However, it is a *LONG* way up a twenty-foot step ladder to tune this and that... A DB or so, I thing, isn't worth the risk of falling and not being able to enjoy life. From two more than 35 foot non-ham associated falls in life, the broken parts don't ever wake up real nice afterwards in life, I can attest ... ;(

What you wanted to know?

--> Sleep well; OS2's still awake! ;)

Ed Hare, W1RFI wrote:
"I do not know of any antenna type where the reactive near field would be nearly 7 wavelengths away from an antenna."

I am tired of this discussion, but think I should respond because someone may infer you meant the reactive near field extends more than 7 wavelengths from all antennas from the statement above.

I`ll refute that very simply.

Look at the FCC charts of "Ground Wave Field Intensity Versus Distance". Chart No. 3 is for 600-620 KHz. All charts begin at 0.1 miles from the antenna. These charts appear in Part 73 of the FCC rules.

Measurement sites are usually no closer than 5 to 10 times the tower height for a single tower station. The closest measurement site will be farther away for a station using a multi-tower array so that the distance to all elements in the array will be essentially equal.

You would not measure in the near field to avoid error. Towers are usually no more than 5/8 wavelength in height, so 10 times the tower height would be 6.25 wavelength.

Broadcast field strengths are frequently quoted at 1 mile from the antenna. Look in any good text. It is presumed that the field strength can be verified at this distance.

Take 600 KHz for example. I referred to the FCC chart which includes this frequency above. The wavelength is 500 meters. A mile is about 1600 meters. That makes a mile 3.2 wavelengths at 600 KHz. Two miles is less than 7 wavelengths.

You wouldn`t challenge the accuracy of a fieldstrength measurement taken 2 miles from the non-directional 600 KHz station on the basis of its proximity, would you?

Best regards, Richard Harrison, KB5WZI

There was a point when I had three 40m antennas plus a 70ft tower packed into a
50' x 110' suburban lot. One was a self-supporting 1/4 wave roof-mounted vertical
with the base 40ft above ground with 4 sloping radials, a classic elevated GP.
The second was a full-wave single Delta loop with the apex at around 65' and the
horizontal side around 25' above ground. The third was a voltage-fed 80m inverted
L, 65' up spaced 25' away from the tower and 65' more or less horizontal. The L
spanked the vertical and the loop on both long-haul dx and stateside ops so I
took 'em both down.

Another thought is the applicability of commonly used ERP figures for FM broadcast.

At 100 MHz, the wavelemgth is 3 meters. 180 wavelengths is about 1770 feet. Most FM broadcast stations have antennas lower than 1770 feet.

ERP is the product of antenna power and antenna gain. The manufacturer specifies the antenna gain whether the type of construction is dipole, loop, slot, or helix. The manufacturer has no idea of the height his product will have over ground or any other surface.

From the nonsense posted in this thread, one might infer that ERP numbers are mostly wrong. I don`t think so.

Best regards, Richard Harrison, KB5WZI

KB7TFW wrote:
"With a 5 element beam 460 feet up on a hill 20 feet above ground at 5 watts what kind of distance should I get?"

The horizon is about the square root of twice the antenna height in feet, but your answer is in miles. The square root of 960 is about 31 miles. Actual mileage will vary depending on atmospheric conditions and the height of the other guy`s antenna.

How loud the signal appears has almost nothing to do with signal strength once the FM improvement threshold is exceeded. That is a principal advantage of FM. How much noise (scratch) is in the signal has everything to do with signal strength. The more transmitter power and antenna gain you have, the quieter the received signal will be. Repeaters work well without automatic gain controls because of the basic FM advantage.

This is a common problem and also applies to dust storms. An RF choke
or a DC-short balun helps.

I would expect the vertical to do a bit better on long haul. Myself, I don't think the overall performance of the loop would be a whole lot different than a dipole mounted at the highest point you hang the loop from. The loop may have a little bit of broadside gain, but not a whole lot. Maybe 1.5-2 db. Myself, I'd probably just put up a dipole as high as I could get it. Much easier than stringing the loop up. Use the vertical if you want to dx. The dipole will work dx, but the vertical will do it better overall, unless the dipole real high in WL. BTW, I much prefer elevated ground planes over ground mounted verticals. It's hard to get enough radials down on the ground at this QTH. And some directions , none at all , as the house is in the way. I compared a ground mount 32 ft whip with 32 radials, and then compared to the same whip at 36 ft, with 4 sloping radials. The elevated antenna was a whole new world compared to the ground mount with only 32 radials. The ground mount wasn't a whole lot better than my dipole at 36 ft to dx. I think it needed more radials. The elevated was 2 plus S units ahead over 2000 miles. And my ground wave was much better. I could work a 100 mile radius with a dead band. Good for locals when the band doesn't support real short skip across town. MK

There's lotsa experience amongst the diehard contesters with precip static.
One widely used trick is to run a wire receiving antenna all over the inside
of the house and just keep crankin'. Loop-based antennas like quads do not
suffer the problem.

Observant and Orthodox can be interchanged. If you observe everything the Torah asks you to, you would be considered Orthodox.

Just used the word to talk about one who observes all of the things one is supposed to do. I know many Orthodox people who don't observe "all" the things they should (including me).

2157. Mobile antenna mount on hood

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-11 00:00:00 UTC
From: zeppss <zeppss@hotmail.com>
Message-ID: <k2pP5.397$Bi3.639@newsfeed.slurp.net>
Source record: 176713

I have an S-10 pickup truck, the new style without drip rails, and have been using a magmount (6m, 2m, 70cm). I plan to get a 60" antenna soon, and don't want a bigger magmount to hold it. A hole through the roof is not acceptable,
the bed has a fiberglass lid on it, and a hitch mount looks like it is too low relative to the body. I am thinking of using a lip mount somewhere on an edge of the hood, maybe the back edge. (RF exposure would not seem to be a problem: most of my mobile use is of short duration at 5 watts,
max. 50w and 35w, and the antenna would extend well above the roofline.)

Anyone have a similar setup, or care to make suggestions?

An open quarter wave would normally reflect as a short. You need to calculate the length with the velocity factor of the coax in mind. Not sure how this will perform as your motor is probably not 50 ohms to the coax. Sounds like an interesting idea. Though. I would be careful using RG174 with this voltage. Better to go with some larger stuff with teflon dielectric. Don't cut and try the coax with the power applied! Also try remoting the receiver antenna away from the motor.

Bill,

Just curious. I have a friend that had an Escort 3 years ago and the owner's manual stated that one must not install radios over about 10-20 watts. Obviously, Ford has corrected that? I knew some else that tried to put an HF rig in a Taurus, and it would choke down everytime he keyed the mike!

Hhhhhey lower 48 types don't bitch till you have to put up with UPS and FED EX. They gladly mail you your package after they have it shipped up here all because some 2 bit company too lazy to put in the U.S. Snail mail. It just as much the fault of the seller for the extra cost . I argued with yaesu to have them send me some part that I need to repair a unit about using the US. postal Service. Told them we didn't have what they want to use. Yaesu stood fast in there decision so I never got the parts and the yaesu unit got tossed. UPS and Fed Ex both sux

I think you mean 'orthodox'; not 'observant'. I don't know why Jeff used that term.

Most walk with family and friends to temple on Saturdays. Conservative and Reform Jews do not tend to honor such restrictions and drive, talk on the phone, and so on on Saturdays.

Jerry, the most faithful of the Orthodox varients of the culture; walk. For a short time a Russian couple, of which the man was a guest lecturer and professor at Texas A&M University, was here. A couple years ago, of the Orthodox variation of the faith, they took an apartment as close as possible to the local small synagogue. On Sabbath, they spent it in the temple, as well as deliberately walking to visit the several nursing homes and the hospital complex also close by.

They chose to seek out the relatively few other Jewish people that were in these institutions, just in service, companionship and an opportunity of a life-time for them to see what the culture was like here. It was interesting to be reminded of this variance in the culture that was so obvious on Saturday when you would see them walking the mile or so this way and that way .. this way and that way.

Sundown Friday night until Sundown Saturday you'd see them. It was a fascinating opportunity to learn first hand, of some of the Jewish history, influence and records of the culture deep within Russia, over in the Siberian area near Perm .. and the Jewish Oblast nestled way above China over there near Korea. These people could talk first hand of it, where for most of us, Jewish or not, all we would ever know would be what little is in the books!

Time, people, perceptions change. That's really good, it's the way we grow and the human race makes progress, we hope! When my Grandfather came here through Ellis Island, before WW II, actually, he was of the Orthodox variation. They deliberately took a house even in the same block as the Temple where they finally settled. Yes, just so they could walk to services on Shabbos. Not only that, but they hired a non-Jewish woman to come in and cook for them on it, as well wouldn't, early on, even turn on or off the light switches!

This of a man whose first job he ever had here, in the first city into which he settled, was to PULL the firewagon! From that, he advanced, when the larger horse-drawn one came, to be a pumper! Yes, one of the ones who stood on either side and moved the hand drawbars up and down as needed! Eventually, he became a tailor .. and .. saw the electric sewing machine invade his hand-work! No, not in the same city, either than the house-in-the-same block deal, but walk still, he would!

Slowly, as life changed around him, his tailor shop was put out of business by the department store that sited near him, and .. right in line with our usegroup thread, he took up a third new career in life, of all things, as an electronic parts counter salesman in a wholesale outfit! Where .. he at way over 50, he learned for the first time, all about resistors, capacitors and ..

antennas!

I was so fortunate! As a kid interested in them as a ham, I was able to talk about them and share with him! No, not in the way I think about them today, but, at least in a practical way .. including his full awareness of what the UHF TV game was all about. Why? Because he was one of the first to get a UHF converter for the set there in the home..

Which .. he always still refused to watch on Sabbath .. Even though, he finally rode to Temple in a car on Saturday! Yet, twenty years after my Grandfather died, the Russian couple as visitors, still were walking!

:)

Did the peaks stay in the ball park of 8.17 dBi at all these heights? If
so then, since the nulls couldn't really get shallower without the peaks
getting smaller, I think you might instead be seeing a numerical artifact.

You need to be careful about trusting the depth of a null as computed
by a program like this with complex configurations (the number of null's
you get when the height is large should suggest that the program views
this as "complex"), since the value is arrived at essentially by subtracting
two big numbers to get a small number and the precision of the result will
be dependent on the number of digits in the big numbers that the program
has managed to keep significant. The intensity at a peak, which will
essentially be the sum of the same two big numbers (more or less) will
have less error on a percentage basis. If the peaks and nulls aren't
changing in unison what you are seeing is more likely an example of why
results that computers produce should always be viewed with a certain
amount of suspicion.

Of course I could be wrong, but when I tried this the peaks really stuck
pretty close to 8.17 dBi even though the null depth was all over the
place. I think it is just an artifact.

Source record: 176629

Hi ,
I have for any years used a 80 metre loop , but never tried so low as 10 to 12 feet. I started at 20 feet and then went to about 35 feet, but here did not seem to be much difference.. The loop was a very erratic shape, a lop sided irregular diamond which started life as a ten metre rhombic... Then the ends joined and the length cut for 80 metres. It worked well on 80 and 40 and to a lesser efficiency on any other band. With the ends of the coax shorted and tuned against ground, was quite good on 160.. It was dismantled to improve appearance of the garden!!! I am thinking about trying it again at low level where it will be inconspicuous!!

Hello,

Has anyone come up with a good design for mounting an R7 or any type of antenna with rather large counter poises on a fire escape? Ideally it would be nice to put it on the roof, but unfortunately landlords are not always cooperative. I would like to be able to extend it a good amount beyond the fireescape so as to not interfere with people, if there is a fire. It would also be nice to be able to pivot or swivel the extension to be able to mount & work on the antenna.

If anyone has any ideas, I'd be great to hear them

Thanks es 73's de

When making the loop horizontal, you get almost vertical radiation, so this wil be very effective on short range reception/transmission. Normally this antenna don't pick up to much noise and this can be an advantage when living in a city

Hi Judd,

A Horizontal loop can be used to good advantage for DX when it is larger than 1 wave length. An 80m (256ft.) Loop fed with balanced transmission line makes a good all round antenna.. a 40m (133 ft.) Loop will likewise work well on 40--10m But a 20m (65 ft.) horizontal loop is not so good on 20m if DX is your primary aim. it's radiation angle is too high.. But contacts will be made even with this default.. it might be a good choice if you wanted say to work 20m WAS.

anyway there is a great discussion of Horizontal loops and their properties found on LB Cebik's page at:
http://www.cebik.com/atl1.html

You probably did not use appropriate choking techniques.
What kind of ferrite did you use? (Many types do not attenuate 372 MHz!)

You are probably better off using a common mode choke for this problem.
I'd try an AC line filter with the appropriate current/voltage ratings.

Thanks for the reply all. I did a little modeling with ez-nec on this. With the outside loop cut for 30 meters, and two loops in the center, one cut for 14,and the other cut for 10. At 30 feet the 30 meters had a take off angle of about 37 degrees. 14 was about 30 degrees. All higher bands had about a 22 degree angle. I put the feed points in the center of opposing paralel wires. Oddly enough, i got a better angle just feeding the 30 meter loop on all bands but 10. 10 was a cloud burner in that scenerio. Feeding the 10 meter loop in the same configuration showed a 15 degree angle , and a very narrow beamwidth, which is ok too. The center loops must be helping on the higher bands, seeing how the outside loop is not resonant at those freqs, but it looks like a viable unit, with pretty fair gain. Not spectacular, but not bad. weight would be about 15 lbs, so easy to handle and not much wind load. The problem is, the input impedance shows about 4000 ohms on ez-nec!!!!! Surely that can.t be the case??? Any ideas on how to fix that???
Thanks again, Judd

6m most activity is around 50.125 and up. You can find some 6m repeaters.
Just look them up in an ARRL repeater book, and give them a try.

HF, 20 meters has the most activity, especially during the day/early evening
hours. After that 40 meters and 80/75 meters.

Hope that helps.

Kent, K9EZ

Judd,
Using a common feed point for a multi-band quad is not the
best idea in the world. For example, the 10m and 20m elements
~will~ interact with a common feedpoint. Used as a single
element antenna instead of a beam driver, there may not be
much affect. When used as the driver on a beam there is quite
a bit of distortion in the radiation pattern.

Hi, At the same question, Kantronics answer that : (be carreful it's a little bit long but i don't know if i can join a file here...)

73' Christophe - F1BDQ

Version 8.2 Firmware Update
Firmware Update Version 8.2 adds advanced digipeating capabilities for GPS/APRS operations by adding four new commands for digipeating--UIDIGI, UIFLOOD, UITRACE, and UIDWAIT--and adding UIGATE to control cross-band digipeating for the Kam Plus, Kam, KPC-9612 Plus and KPC-9612. See the GPS/APRS discussion below. In addition, 8.2 versions for the KPC-3 and KPC-9612 are upgraded so that their command sets are more like those for the KPC-3 Plus and KPC-9612 Plus. For example, MODEM mode has been added so you'll be able to copy the NWS EMWIN weather broadcasts. See description of EMWIN below.
If you've skipped over one or more of last year's upgrades for your TNC, don't be concerned; 8.2 firmware incorporates the major features of the previous upgrades. The Version 8.2 Firmware Upgrade Manual Addendum, shipped with the firmware, includes a full description of the new digipeater commands and commands modified or combined with other commands since the last update.
Since documentation is not included for previous updates, KPC-3 and KPC-9612 owners might wish to purchase our newly written KPC-3 Plus and KPC-9612 Plus manuals which incorporate material from previous updates and are a great reference source. These manuals contain over 280 pages of information, including 60 pages of operational information on the various VHF/UHF digital modes, an 80 page Command Reference, and an extensive index. The operational chapter includes sections on the following: the packet mode of operation, remote access to your TNC, the packet personal mailbox (PBBS), working with a full service BBS to forward messages, GPS interfacing, the KA-Node networking system, WEFAX (for KPC-3 and KPC-3 Plus), the NEW EMWIN mode, KISS mode (for TCP/IP operation), and DAMA mode (the European node system mode).
Since the Version 8.2 update is not available for KPC-2, KPC-4, or KPC-2400 owners (due to their limited memory space), this may be an ideal time to consider the purchase of a new KPC-3 Plus or KPC-9612 Plus. Advanced GPS/APRS Digipeating: Amateurs are using GPS receivers, a packet unit, and an FM transmitter to report the location of their vehicles or stations to others. Their broadcasts use one-way (unproto UI) packets, to report call sign, latitude and longitude. Packet stations hearing these broadcasts may display the positional information, often using map-based programs such as APRS. To extend the range of reporting, it has become common practice for the mobile stations to use digipeat paths containing generic digipeater

names, such as RELAY and WIDE. Using these names (aliases), there is no need to recall and enter specific call signs during a trip.
In response to requests from many GPS and APRS enthusiasts to more fully support "generically named" digipeater activities, we've added four digipeater commands to the 8.2 firmware, that provide alternative ways in which to digipeat using generic call signs. First, the UIDIGI command allows up to four additional digipeater aliases and supports a swap of MYCALL for the alias name during digipeating. Second, the UIFLOOD command adds the ability of the TNC to digipeat several times, frames that contain only one digipeater address, such as WIDE3-3. Here, the ssid (-3) is decremented each time the frame is digipeated and each TNC digipeats such a frame only once. UITRACE does the same but adds the digipeaters MYCALL address to each outgoing frame, creating a return-path record, a "trace."
For You Techies out there, here's a brief description of each new digipeating command:
UIDIGI ON [+|-] call1[,call2[,call3[call4]]]
Up to four call signs can be specified for special digipeater duty. If any of the UIDIGI calls appears in the to-be-digipeated field of a UI packet, and if MYCALL does not appear in the source field or any of the has-been-digipeated fields, the UIDIGI call in the to-be-digipeated field will be replaced by MYCALL with the H bit set and the packet will be digipeated.
UIFLOOD name, n, [ID|NOID] (n=0-255)
When a UI frame is received with a call in the to-be-digipeated field of the form name'x-y (e.g. WIDE'3-3), the ssid is decremented and the UI frame is digipeated without the H bit set if such a packet has not been "seen" for the last n seconds. If the optional ID parameter is set, the MYCALL is placed in an additional digipeater field with the H bit set.
UITRACE name ,n (n=0-255)
This command is similar to UIFLOOD except that the MYCALL is inserted as a has-been digipeated address. Thus digipeated frames grow in duration as they are digipeated several times.
UIDWAIT
When OFF, digipeaters retain first channel access. When ON, digipeaters must compete with normal packets for channel access (using PERSIST).
NWS EMWIN Broadcasts: The NWS Emergency Managers Weather Information Network (EMWIN) is a wireless, direct-to-computer information service that the National Weather Service (NWS) provides with help from the Federal Emergency Management Agency. The NWS feeds a constant stream of weather information (@ 1200,8,N,1), from around the world, to a satellite orbiting the Earth. Many cities are coming on line now to capture this stream and rebroadcast it on fixed VHF FM frequencies., usually just above the 2-meter amateur band, tunable with most rigs. With an FM receiver or scanner, a KPC-3, KPC-3 Plus, KPC-9612, KPC-9612 Plus, KAM Plus, or KAM with Enhancement Board, and PC with communications software, you can copy these broadcasts. The content of the broadcasts may be plain ASCII text (copyable with Pacterm - shipped with Kantronics TNCs) or graphics (copyable with "WeatherNode" software, stocked for sale by Kantronics).
To copy the broadcasts, simply cable together the equipment mentioned above, tune your VHF FM receiver to the local EMWIN frequency, set the KPC

interface command to MODEM, and follow the text on your PC screen.
Please be sure to select the right KPC model(s) for your update(s); the
EPROMS (firmware) are not interchangable.

My son uses small value capacitors from the motor leads to the case on his electric powered RC cars for just that reason. Find some low value caps (20 to 300 pF) and put one from negative to case, one from positive to case and one across the positive and negative. This should take care of it. If you have a scope you could find the exact frequency of the noise and calculate the cap value otherwise you'll need to experiment. Remember to keep the cap leads as short as possible.

Bill Nelson wrote:
Not quite. ERP is the sum of the transmitter output power and antenna gain - minus feedline, filter, coupler etc losses.

If one were to do a db accounting, one would add gains and losses for a net power output in dbm or dbw, etc. DB are logarithmic units, so that to multiply you add the db.

But, ERP is the product of antenna gain (the ratio, not the db) and the power delivered to the antenna (which has already discounted feedline, filter, coupler, etc losses.

If a transmitter delivers 25 KW to the antenna which has a power gain of 4, the station has an ERP of 100 KW. It delivers the same power to a receiver that a 100 KW transmitted signal into an antenna with a gain of 1 (0db) would deliver to that receiver, with the same locations involved.

The antenna in the example has a gain of 6 db, but that is not the unit used to compute ERP. The simple power gain (4) is the unit always used in a case of this magnitude in calculating ERP. The same process is used, regardless of magnitude, when calculating ERP.

Best regards, Richard Harrison, KB5WZI

I once had a 50 ft Rohn 25 set in a cubic yard of concrete, unguyed, with a tribander and stacked Cushcraft 11 el 2 meter yagis on top. It stayed up FB for about 6 years, through some pretty daunting winds, and would probably still be there if not for one late winter day when Mother Nature played one of her tricks...

Feb 28, '82 began sunny and warm, a really nice late winter day portending an early spring. But in late afternoon, a Blue Norther blew in, rain changed to freezing rain, the Rohn 25 became a huge 14 inch icicle, and the heavily gusting winds from the north really whipped it around. I wondered if it would stay up, and late that evening as a virtual blizzard howled away, it came down, falling south, kinked over at the base just above the concrete. It fell across a storage shed and the end of tribander boom just nicked the roof of the house, taking down the rain gutter.
One of the Cushcraft 11's was history, but the other and the tribander were in pretty good shape for the ride they had gone through. They now reside atop the replacement 60ft unit, also set in a cu yard of concrete, which has a single set of stainless steel guy cables at the 50 ft level, and over the past 15 years has withstood everything Mother could toss at it, so far.

Brian Kelley can explain it in Mechanical Engineerese, but I know that what happened is that the buffeting winds caused the tower to whip back and forth, and with the heavy ice load, a strong wind gust caught it leaning the wrong way, and with the added ice load it overpowered the lower part of the tower's mechanical strength to withstand it all, and over it came. Note that the 4x4x4ft concrete base didn't budge.
While such weather events are rare in this part of the world, I am lucky that it wasn't situated where it could come through the middle of the roof - mine or someone else's. No more freestanding rigs for me. And none situated where it could possibly come down on property belonging to others. The present version is located alone in the middle of a 150x150ft lot. If it should succumb to one of Mom's whims at least it misses everything but the earth.

I'm not sure how many people use your fire escape, other than on an
emergency basis, but anyone touching your antenna could get a rather
nasty shock, and that could be dangerous on a fire escape, where a
fall could be deadly.

Also, a metal fire escape, with all of its odd-length metal pieces,
could play havoc with an R7's radiation pattern, or even produce
harmonics.

You might look at a B&W AP-10, a window-mounted whip. I had good luck
with one in a 3rd story apartment, many a moon ago.

I have had a Cushcraft MA5B mini beam on the tower since January of this year, and have been
absolutely amazed with it's performance.

However, over the last week, the SWR has shot throught the roof on 20m, and has increased
somewhat on all of the other bands. The SWR previously was spot on across all bands. I haven't
had a chance to get antenna down yet due to high wind conditions, but would be interested to hear
from anyone who has had similar experiences, or who has any suggestions regarding possible cause.

Thanks in advance,

Russ
M5ADY

From: Cortland Richmond <ka5s@earthlink.net>
Message-ID: <3A0EE8E2.FB3583EA@earthlink.net>
Source record: 176651

I used five inch magnets from commercially available mag-mounts; two of them come from flea-market monster "CB" mounts and required painting and weatherproofing, but they work fine. The plate is aluminum from a local scrap yard, around one-third of a circle, about 16 inches from the small end to the circular portion. On the front of the circle I have five magnets, on the back, which is cut off short, I have two. The antenna you see is actually a bit large for that mount, and a more prudent design puts the coil a bit lower with a slightly smaller top hat on an 18 inch Hustler (TM) mast.. In order to make installation easier I used an Outbacker (TM) base, with integral spring. This is one of the few springs I have found strong enough to hold a small bug-catcher upright at most highway speeds. I have since obtained a military antenna mount some fifteen inches tall whose spring is 5 inches wide, but I have yet to adapt that for the mount you see.

Really, this is as large as a sane person -- mostly sane -- would try for a magnetic mount. It can only go near the hatch, as a good ground strap is absolutely necessary. But the sheet metal on these small cars is deficiently strong, and I fear even with a doubler inside I might tear a hole in the car's roof.

The magnets also must be aligned parallel to the roof where they are. If they are only approximately so, the mount can (has!) separate under some conditions of acceleration, relative wind and side-to-side motion. In addition, trees are a hazard; I lost a side window once when I used a guy; a branch snuck in behind the guy and pivoted the mount off and into the window. $300! Ouch!

Regards,

Cortland

I ran 100 watts from a Taurus for some years, had lots of fun working JA's
on 80 CW, breaking DX pileups on 40 CW, and no problems with the engine.
However... the fuel pump on the Taurus is notoriously noisy.

Yup!

Nowadays, cars <<can>> do some wierd things when subjected to RF. When
I first installed my screwdriver my rear defogger indicator would glow
and modulate as I talked. Sometimes the windshield wipers AND the washer
would come on! LOL! I wound 6 turns of the coax around a small dowel
near the antenna feedpoint and cured it.

I guess it depends on what is is... Amazing the convoluted logic it takes to make one appear they are abiding by the rules.

One wonders if God parses his laws as finely as those who speak for him.

While none of this is my concern, I do find it rather curious.

Ed Hare, W1RFI wrote:
"If you want to make far-field measurements of an antenna over ground, you will have to be 2D^2 / lambda away from the antenna, with D = the largest dimension of the antenna system, including its height over ground."

That makes no sense for great antenna heights.

As anyone can see, for an antenna many wavelengths above ground, the required minimum distance for measurement becomes for practical purposes 2 h squared, where h is the antenna height, with Ed`s interpretation.

The higher the antenna, the farther away you would have to be (by twice the square of the height) to make valid measurements. That is not so. valid measurements are made over ground every day. You don`t have to go into outer space (if that were even helpful with Ed`s interpretation of the formuls) to make useful measurements. You don`t have to have an anechoic chamber either, but they are nice.

The purpose of the formula that Ed quotes is to ensure that the wavefront has flattened to a plane wave which produces no more than 30 degrees of phase error. S , D, and lambda are all in the same units, meters, feet, or wavelengths, your choice.

Ground effects must be considered, but that means that you must be rather close to the antenna so that the reflection from the ground will NOT bother you in making the measurement. You do need enough distance from the antenna to get a plane wave at the capture area (aperture) of the antenna being tested or the aperture of the test antenna. Reciprocity says you can either receive or transmit with the antenna under test to determine its gain and pattern.

I used lambda = 1/3 foot for my 3 GHz antenna.
I used D = 3 feet for the longest dimension of my aperture.
S = 54 feet
S is still 162 wavelengths for this antenna which was 180 wavelengths high. The long minimum distance is because the minimum dimension of my aperture was very large in terms of wavelength and it gets squared. But in an antenna this removed from ground, height is no longer a factor, presuming you can keep the effect of the reflected energy under your control.

Best regards, Richard Harrison, KB5WZI

Source record: 176661

the answer is simple - go as high as you can! 35 ft will NOT be as effective for most all communications on 20 as 54' will - especially DX!!!

After running EZNEC and YT on this scenario there is 3 db difference at ALL relevant angles for the 50' vs the 35. And 5 db for a 65' compared to a 35! Unless you truly want local coverage I would recommend the 50 foot height without hesitation. The high angle lobe is down 11 db from the main lobe and really is not going to rob any energy to speak of - the frontal lobe of the main beam covers ALL relevant angles (there is NOTHING above 18 degrees per YT - at least nothing outside of a couple thousand miles). The frontal lobe is centered at 18 degrees (-3db @ 8.7 and 28 degrees) whereas the 35' height is centered at 24 degrees and extends up to almost 39 degrees.

Signal should not be a consideration here - only other factors such as funds and neighbors! (and actually the neighbors would be better off with the 50' as well).

Cortland,

We seem to agree on the old adage "Beauty is in the Eye of the
Beholder". I think the same thing about my "Bug-screw"--which is a
3" dia. screwdriver! The "beauty" is in the way it performs. Today,
since the WX was nice here in NC, I got out in the yard "piddling" and
doing field strength measurements. I used a smaller screwdriver, an old
Master Mobile center-load, an ancient antenna called the Bay Mobile (the
predecessor to the Webster Bandspanner, and a ham stick. As expected,
the Big Ugly came in first, the smaller screwdriver #2, Master Mobile
#3, Bay Mobile #4, and the ham stick didn't even move the meter! LOL!
Just what I expected! I just LOOOOVE them Big "Ugly" antennas!

How about a number of stout Rebar pieces drilled into the Bed Rock? I
wish I had such material available where I lived. If oversized holes
were drilled into the rock at an angle, and Epoxy used to retain the
Rebar, which was bent vertical after leaving the rock, the result could
be unequaled support, unavailable without great expense!

Message-ID: <3A0F6C3B.C6705389@hiwaay.net>
Source record: 176666

Please forgive the digression, but- there are probably smaller differences in insertion loss among the manufacturers than there are in other, important characteristics. In my experience, the two main problem areas have been poor thread quality (the cast threads are the pits) and failure of the center sleeve, on UHF connectors.

Any connector that is in service with repeated connect- disconnect operations will Hell to use, if the threads are bad. The same service will open up the sleeve and result in poor (or no) connection, if the sleeve is skimpy or has low spring quality.

There has been a lot of very good advice on this NG on the subject of N vs UHF connectors. THe consensus from the better Guru's is that the N type are rarely really needed, unless you are at UHF with QRP and long runs, in which case you should be using other means of transmission, anyway.

Good luck- Bill

I have a setup like you describe on my Ranger pickup. It's a lip mount at the left/rear edge of the hood with a 49" dual band MFJ-1412 antenna. It allows me to pull in my garage and just barely hit the 7' tall door opening with the antenna. Performance is good but not necessarily any better than what others in this area get (on 2m) using a simple 1/4 wave antenna mounted in the roof.

Source record: 176621

Hi Group,

I have a dc motor giving my receiver a noise problem. The receiver is a remote on 372.5 MHz and the dc motor is generating some noise which limits my flea power range to about 25 feet. In generally, I get 200 feet without the motor on.

I have tried bypassing the motor leads to motor chassis ground and pulling a ferrite bead inline with the motor power. This has not really helped. I can not relocate the reciever either.

So, I would like to try a different method. Place a open ended RG-174 coax cable across the motor line. As I recall, if the RG-174 is electrically 1/4 wave then the open at the other end becomes a short at the generator? true/false or is it 1/2 wave?

If so, then, what length would I cut the RG-174? And what is the equation?

Also, the motor is 230V so is this a safe voltage for the RG-174.

Many thanks!!!

Paul

I am looking for the adjustable coil for the SLV. I have the 20' Black Widow already, but need the rest of the parts to build the antenna. Can anyone help? Thanks, Mike.

When said views are posted in a public forum!

You wouldn't have to ask very far to determine that people don't come
much more "lightened up" than moi!

Despite what would appear to be an off topic subject for this forum, I
found this to be one of the first of a religious nature that was
unoffensive, and purely informative (even I actually learned something).
My response was more aligned with an exercise in logic, and not intended
to criticize one's religious beliefs.

What about getting one of those stainless tool boxes for right behind the cab? There you could drill holes to your heart's content, the antenna would be right in the center, and when you trade, just remove the box for the new truck.

Steve, from where do you get the idea RF currents 'stop' at
3 to 4" below the surface ?

It is not that radials greater than 6" deep 'defeat the
purpose', it is just that there is not much more benefit to
be obtained by digging deeper.

Compared with wire diameter, 6" is quite deep enough to
obtain an adequate connection between wire and soil.

No ERP calculation can be accurate unless it includes the gain obtained through the ground reflection. In the case of an antenna that is designed not to radiate energy downward, the ground reflection can be minimal, so it may be possible to use the free-space gain of the antenna very handily to calculate ERP.

As an aside, to calculate ERP is referenced to the gain of a half-wave in free space, so the easiest way to use it is to start with the antenna gain in dBd.

BTW, 6 dB and a power gain of 4 are precisely equivalent. Either can be used in calculating ERP.

>That makes no sense for great antenna heights.

Perhaps my choice of words led you to believe that I am saying something different than I intend.

It applies equally to great antenna heights. If you want to measure or calculate the far-field pattern of an antenna *over ground* (this does NOT mean the calculate the free-space pattern, it means the pattern that one obtains in the real world when the antenna is over ground, ie all the lobes and such that happen when the antenna interacts with the ground) one must be very very far away from the antenna.

This does not apply to making calculations of free-space patterns from the data extrapolated from measurements made on an antenna range. That can be done very nicely in the radiating near field as determined by the dimensions of the antenna itself, although the methods to calculate out the ground reflection to obtain an actual free-space pattern can be a bit interesting.

>Ground effects must be considered, but that means that you must be
>rather close to the antenna so that the reflection from the ground will
>NOT bother you in making the measurement.

This is the part of my statements that you have misunderstood. I originally said that to measure or calculate the pattern that one gets when one places an antenna over ground, one must be as far away from the antenna as I have stated.

From the statement that you made above, it looks pretty clear that you misunderstood me to mean that one had to be that far away to make ANY measurement of the antenna.

One cannot make a measurement of the ground-reflection pattern under circumstances where the ground reflection will not bother you when making the measurement.

I think you and I have been arguing apples and oranges, Richard. Perhaps this could explain why you think my statements to be nonsense.

2232. Re: grounding question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-13 00:00:00 UTC
From: Stephen Verbil <sverbil@usa.net>
Message-ID: <3A0FF538.AEB63C8A@usa.net>
Source record: 176590

I am very concerned about one part of Ed's letter: I believe he is looking for a way to tie the building electrical ground system together with the antenna ground system. I would guess, Ed, this is because you have learned somewhere about the problems that ensue when you have different, independent grounds. Rick did a good job dealing with the RF issues, I'll just stick with safety...

However, the way to accomplish that is *not* to pick up a 'ground' at an outlet that happens to be nearby the coax' entrance to the building. The safety ground available there is designed to provide a path to ensure (among other things) that the protection for that circuit will trip. It is not designed to carry antenna discharge currents!

Excerpted from the National Electric Code, Chapter 8, Section 810 which covers, among other things, amateur radio transmitting and receiving equipment,

the ground connection from an "antenna discharge unit" :

(f) Electrode. The grounding conductor shall be connected as follows.
1. To the nearest accessible location on the following:
a. The building or structure grounding electrode system as covered in Section 250-50
b. The grounded interior metal water piping system as covered in Section 250-104(a)

c. The power service accessible means external to enclosures as covered in Section 250-92(b)
d. The metallic power service raceway
e. The service equipment enclosure, or
f. The grounding electrode conductor or the grounding electrode conductor metal enclosures; or
2. If the building or structure served has no grounding means, as described in (f)(1), to any one of the individual electrodes described in Section 250-50; or

j) Bonding of Electrodes. A bonding jumper not smaller than No. 6 copper or equivalent shall be connected between the radio and television equipment grounding electrode and the power grounding electrode system at the building or structure served where separate electrodes are used.

and finally...

(h) Size. The grounding conductor shall not be smaller than No. 10 copper, No. 8 aluminum, or No. 17 copper-clad steel or bronze.

So... your connection goes to a grounding electrode (your rod driven into the ground. You should interconnect it, and when you run the interconnection you need to make a straight run to the point you use (lots of folks use the service entrance enclosure and its associated ground connection). Normal house wiring doesn't use #10 sized ground conductors.

In summary, connecting to the ground available in an outlet won't accomplish what you want. And. being a GFI outlet, there's a good chance that if any stray RF is on the outside of your coax, you'll trip the GFI and turn off anything attached to that outlet.

Might be interesting with Christmas lights plugged in there in the winter :-) ...

==========
Good Morning Frank

In the context that hams use QSO -- it does NOT mean Quasi Sinusoidal
Oscillation.
QSO as used in communications was taken from the Q-Signal lists of the old
telegraph/wireless radio days.
On 1st July 1913 the Q code became an official international information code,

updated as changing circumstances demanded to include new codes relating to
such matters as aviation and maritime. Amateur Radio Operators used it also
since
many of them were radio/telegraph operators as well.

Widely used by radio amateurs operating CW, today's Q code has
slightly different meanings but is still very similar to the 1913 version.
One of the great benefits of using the Q code is the pleasure in being
able to communicate with overseas operators who may not be fluent in
your language.

Strictly QSO means:
QSO Can you communicate with ... direct or by relay?
I can communicate with ... direct (or by relay through ...).

Hams have taken the "communicate" to mean a two way conversation between two
Ham Stations. Thus the phrase "Thanks for the enjoyable QSO" translates to
"Thanks for the enjoyable conversation"

Ed Hare, W1RFI wrote:
"No ERP calculation can be accurate unless it includes the gain obtained through the ground reflection."

ERP is calculated by multiplying measured power, at the FCC designated power determination point, times the gain of the antenna (as a simple ratio). The reference antenna for this is a dipole, which is specified as having a gain of one.

No ground reflection is involved.

Ed also wrote:
"As an aside, to calculate, ERP is referenced to the gain of a half-wave in free space, so the easiest way to use it is to start with dBd."

Anyone should use what is easiest and accurate. All FM broadcast antenna gains are given in dBd, as Ed said. That adds no clarity so I didn`t add it to my explanation. The only items that matter are (1) the antenna simple gain ratio over the standard, and (2) the designated power output of the FM transmitter.
If the antenna multiplies the power by concentrating it approximately toward the horizon at the expense of radiating it toward the zenith, by a factor of 4, the Effective Radiated Power output of the transmitter is multiplied by a factor of 4. That is the definition.

Ed also wrote:
"BTW, 6 dB and a power gain of 4 are precisely equivalent."

Well, not precisely, but close enough. DB and power gain represent the same thing, a power ratio. So, either can be used to calculate ERP. I would suggest using the easier. The definition of ERP is designated power times power gain.

That's the big glitch. Ideally the magnets would be mounted to the frame via spherical swivels so that they find their own "homes" on the contoured surface. I think I just had a brainfart on how to do that, bolt the magnets to the frame via spherical bearing rod ends. Yessss . !
>
Fact is that I'm headed off in a somewhat different direction. My close-in goal is to mag-mount one of the 20 foot collapsible composite fishing poles per the w6mma St. Louis Vertical on the roof for stationary portable ops vs. undeway mobile ops. Go find a big, quiet hill out in the boonies, get the pole outta the trunk and push it up, drape a few radials around, etc. In this scenario I wouldn't need a flock of magnets. But the problem is the same, where the heck are the magnets?

How high, Ed? Half the distance to the moon?

I`ve found a 1982 edition of the ARRL Antenna Book. On page 15-24: "The presence of the ground further complicates the range selection, not in the selection of S but in the exact location of the source and test antennas above earth."

On page 15-25, a sample calculation of;
Smin = 2D^2 / lambda
is made for a 7-ft dish at 1296 MHz (lambda = 0.75 foot). Smin = 130 feet.
The distance above ground is not added to the 7-ft dish dianeter. It is not involved in the example at all.

At half the distance to the moon, the curvature of the earth would be great enough that the antenna would appear to be in free space.

Let me try again here. A real antenna over ground exhibits peaks and nulls. Again, my contention is that to measure that pattern, including the peaks and nulls, one must be in the far field of the antenna system, including the distance between the antenna and its "image antenna. How far from an antenna do you believe one has to be in order to measure the peaks and nulls of the pattern of an antenna over ground?

Have a one-month-old 2001 Chev Silverado LT that I just don't want to drill holes in, nor do I want to put scratches in the clearcoat with a mag-mount.

Anyone have a favorite way of mounting a dual-band antenna (2M/440), maybe on the bed rails or in a stake pocket?

Thanks in advance for any bright ideas.

73, Hans, K0HB

==========
From the article by Kenneth Brown G0PSW at URL:
http://www.ac6v.com/pagear.html#QZ

Some time later (after 1913) came the Z code, running in parallel with the Q code.
This originated as a company code of Cable and Wireless with
application limited, in the main, to high speeds machine morse
operating at speeds of typically 120wpm. Widely used by many
countries, including Germany, the Q code and Z code continued in use
throughout the war. After the war high-speed morse became less
widely used and was replaced by other forms of traffic communication
such as RTTY and facsimile. The Z code, therefore, gradually went out
of fashion and slowly disappeared. Examples of the Z code include
ZAA you are not observing circuit discipline, ZAN we can receive
absolutely nothing, ZST send slips twice, ZAP acknowledge please
and there were lots of others.

Hi Richard and Ed:

Hope you guys don't mind my two cents.

Both of you are correct so long as your discussion is kept in the perspective of the example discussed. I think you're comparing apples and oranges.

In Richard's example above, you have a 7 foot dish at 1296 MHz. This antenna would have an elevation beamwidth of approximately 7 degrees. If the antenna has good sidelobe performance, there would be virtually no antenna image in the ground and the antenna's height above ground is not considered in determining the distance to the far-field. In this case, the antenna far-field is approximately 130 feet (171 wavelengths). To measure a reasonable far-field pattern of this antenna you should have a range of at least 130 feet. Even when measuring large aperture antennas on long ranges, its still good to watch out for ground reflections that may exist and many times, diffraction screens are used to make ground effects "invisible" to the measurements.

Now in the case of HF antennas over ground, we go back to Ed's comments. With a Rhombic or horizontal dipole over ground, there will be a ground image as a function of the dielectric constant and conductivity of the earth. If the antenna was on a 70 foot tower, then the "antenna system" dimension would be 140 feet and the approximate far-field would be at a distance of 1194 feet (10m wavelength) which is about 36 wavelengths. Note that in terms of wavelength, this is significantly smaller than the example above at 1296 MHz. That's why HF antenna patterns can be measured on a much smaller physical ranges than high gain microwave antennas. Another factor to consider in all of this is the "strength" of the antenna image in the ground. Typically, at HF frequencies the level of reflected energy may be down as much as 3 dB and there will also be some phase shift. On very poor grounds, the antenna image may be negligible. Still, ground reflections

will impact antenna measurements.

As a general rule of approximations, three fields exist about an antenna as follows:

1) The reactive near field from a distance of 0 to approximately 0.62 * sqrt(D^3 / WL)

2) The radiating near field from 1) to approximately 2 D^2 / WL

3) The far field from 2 D^2 / WL

It is important to understand that these are general approximations.

Steve VE9SRB

I know that you don't want to drill holes, but right above the interior light is enough room to mount a drilled thru type mount w/ a 90 Deg. fitting. If you have a console up there, you have more space to move it to the middle of the roof.

THere are stake pocket mounts in QST & the other mags. I'm sure that HRO & AES have them.
I just think that the pattern will be pretty skewed.

Ladder racks might help....

Interesting comment, Reg . . .

I thought that any ohmic contact between buried radials and the soil was
strictly incidental and played no role in the operation of the radials:
return current collection.

If "connection between wire and soil" is involved in radial operation
and is of importance, why is it that insulated radial wire seems to work
well? Or are such radials sub-par?

2250. 2M Groundplane radials touching snow?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-13 00:00:00 UTC
From: Matthew Delaney <delaney@ucs.net>
Message-ID: <t10ctp9cg5kl41@corp.supernews.com>
Source record: 176608

I have a 2M ground plane mounted on my roof (actually hanging off my gutter due to the need for a semi-stealth installation), but the 2 radials that hang over the roof only clear it by an inch or so. Right now it's working very well (very low SWR), but here in the NE US, snow is just around the corner. If I get some snow on the roof and it starts to bury the ends of the radials against the roof, will this have a drastic effect on my SWR? If it will have a major effect, I can raise the antenna somewhat (it's supported through a T shaped assembly of PVC pipes, with the cross part of the T hanging off the gutter). However, if it's not going to be major, I'd rather not raise it anymore, due to the loss of some of the stealthness and the extra weight on the gutter.

Thanks,
Matthew Delaney, N2MDB

Steve, VE9SRB wrote:
"Another factor to consider in all this is the "strength" of the antenna image in the ground."

Thanks, Steve, for an illuminating view.

One way to illustrate the decline in importance of the ground image of an antenna as the antenna`s height increases may be an optical analogy.

I`ve avoided this analogy because I`d rather zero in on an agreement than to enlarge the argument over what the analogy means.

Imagine a mirror. Trim a cardboard sheet to exactly cover the mirror. Keeping the cardboard in the line of sight and parallel to the mirror, remove it until it is an inconspicuous dot in the mirror`s reflection. At that point the reflection and the cardboard are irrelevant to each other.

Something roughly similar happens between an antenna and its reflection in the earth. The analogy is admittedly strained but in a general way it shows what happens with an antenna very far from earth.

Best regards, Richard Harrison, KB5WZI

Source record: 176617

For multi-band working there is no particular length of dipole which is significantly better than another. Don't bother too much about whether it is resonant or not. HEIGHT is a more important matter. The higher the better on the lower HF bands.

If you are unable to erect a full size dipole for 160m then put up the longest you can and turn the ends through a right angle, either sideways or downwards, to increase the overall length.

The only rule of thumb - efficiency falls off rapidly when overall dipole length is less than about 0.3 wavelengths at the the lowest operating frequency. That's about 160 feet on 160m. So your 180 feet should be fine even if you are unable to extend downwards at the ends.

Use 450 ohm ladder line or 600 ohm open wire feeder all the way to the shack if you can manage it. Use a choke-balun at the shack end and you will need a simple tuner. Be prepared to adjust the length of line for occasional coarse tuning purposes.

Hi I have a question for all. I am about to build my own 6M {50 ~ 54 Mhz}
cavity
cans, but I need some help big time. The building of the can is not a
problem, however
the size of the coupling loop is ! Does anyone have a 6M or 10M cavity can
that
that they could give me details on size and all that good stuff for the
making of
the loops? Please no, I guess it's this big or stuff like that, but real
facts on size
in one.

2261. grounding question

I'm putting up an inverted V antenna in some trees on my lot and I have questions about grounding. The shack is on the second floor in a room over the garage. I've dug a trench, laid in some PVC conduit and I've got sufficient RG-8 to go down the tree, through the conduit, and back up to the second floor. At the garage, where the wire will be entering, I've driven an 8' copper ground rod.

Q1: when I tie the antenna ground system to the house ground, can I wire it into the ground of a GFCI outlet that's conveniently nearby?

Q2: what kind of lightning arrestors are available for this installation?

Q3: how exactly do I ground the cable? I could strip the coax jacket and solder the copper ground wire to the sheild, but what's recommended as far as weatherproofing? Would it be better to have a connector?

Thanks for any help with this.

Bob,

Thanks much for the Reply.

A couple of things..

No one uses the fire escape. I suppose it is only there for its sole purpose. No one even puts any plants out there.. since it doesn't get enough sun. As far as getting a shock from the antenna goes.. I am not home all the time.. and when I am I can look right over my shoulder and see the fire escape. The reason I asked for a design was because I want to extend the antenna beyond the fire escape so that none of the problems you mentioned below would occur... I've been to a machine shop, but they need exact specs and since I've never seen or done something like this before, I wanted to see if someone had any ideas.

Tnx agn

>Simple and low cost if possible.<

Get some RG-58, some wire, and make a simple dipole. Hang it from the barn roof or a tree and make a sloper or an inverted "V". Should match to your rig without a tuner and work great! With conditions the way they are right now, that extra 3-5 dB you'd get with a beam won't amount to.....well.....a hill of beans.

I have erected many antennas and towers. After studing about RF grounds, I found that buring ground radials below 6" ground level defeats the purpose. The RF stops at 3 to 4" of ground depth and dissapates. They will work for lightning protection, but do they really work for RF?

Steve

Source record: 176576

Hi Ed--

Grounding for DC from the second floor is easy, but grounding for RF at 28 MHz is nearly impossible because the wire will be too long in terms of wavelength. I think the best way to keep RF out of the shack is by making sure the outer surface of your antenna feedline is "choked off" against RF currents. If it isn't, any ground wire you install may actually become part of the antenna system!

To prevent what are called "common-mode RF currents" from returning to your shack, make sure you use a balun of some sort at the antenna's feedpoint (ferrite sleeves, coils of coax, or something), and also wrap a few coils of coax at the back of your rig and tape them up. If no RF current can come back down the outside of you feedline, the chassis RF potential on your rig should remain "cold" and you can then connect a wire to ground rods that will act as a DC ground without radiating RF. That's the condition you want to create.

Up here in NH, I live on a sandhill with terrible ground conductivity and I don't even attempt to ground my station for RF. Instead, I choke all my feedlines to create a high impedance condition for RF current return (rather than a low impedance condition through RF grounding). I also disconnect my feedlines and master power when I'm not using the station to avoid problems from thunderstorms or severe snow static. In the past three years, I've lost two Fax machines, a modem, some lightbulbs, and a couple appliances to lightning--but never a radio. If your station isn't connected to anything (including a ground), nothing will happen to it unless the house burns down around it!

Well, if you do make some kind of extension, make sure the darn thing
is sturdy. I used to have an R3, and it took a fairly stiff and heavy
2" pipe to provide a sturdy vertical mount for it. My neighbor had an
R7, and he had a similarly sturdy vertical pipe mount. If you're going
to extend outward from the fire escape, the extension pipe will need
to be bracketed in some kind of triangulation design. The R7 is
heavier than it looks, especially when the wind starts blowing. (I
originally tried putting my R3 on a wooden post, and nearly broke the
thing before I went to the heavy metal pipe.)

Good luck!

Source record: 176578

...not to mention large (1/2 wave in size for each cavity) - you'll need at least two, probably four to do it right, and they don't take too kindly to getting banged around, or to temperature changes, and they are extremely narrow-banded, not frequency-agile. So forget it....

In the "old days", they were small mobile duplexers available in the VHF range and UHF range. The VHF ones for IMTS telephones were approximately 6 MHz split, I think, and they were rather lossy... the UHF ones (also for IMTS system) were set up for 5 MHZ split, and some hams *are* still using those so they can run full duplex while chatting on their favorite linked systems.

> it leaning the wrong way, and with the added ice load it overpowered the
> lower part of the tower's mechanical strength to withstand it all, and
> over it came.

>
Cometh another short-form lecture on applied mechanics, the basic field spanning several engineering disciplines which deals with the behavior of structures under load.
>
The deal goes something like this: An unguyed tower sticking up out of the ground is a simple "cantilever beam" as are are the wings of an F-16. All beams will fail when loaded to a point which exceeds the material strength. In the case of low carbon steel which is what Rohn uses the failure stress ("yield stress") is around 30,000 Lbs. per square inch. A one inch square steel bar pulled like a length of rope is on the edge of failure when the load goes up to 30,000 Lbs. Failures can occur due to either compression (column collapse) or tension (break rope). Tower legs usually fail first as columns vs. tension failures. Which is why when you examine a failed tower you usually see one leg really crumpled and the other two legs just bent over. The crumpled leg should be on the downwind side of the tower which was in compression when it crapped out.
>
For simplification visualize a 10 ft. length of pipe poking up out of a concrete base rather than a complex structure like a tower. Pull horizontally (wind load on the antennas) on the top of the pipe with a force of 200 Lbs. If you multiply the wind load by the length of pipe you get a quantity called the "bending moment", in this case 200 x 10 = a 2,000 ft-lb bending moment. The bending moment in a simple cantiliver beam varies from zero at the top to it's maximum value at the point where it enters the concrete.
>

Whether or not a 2,000 ft-lb bending moment is enough to fail the pipe obviously depends on the geometry of the pipe. Common sense indicates that a 10" diameter pipe with a 1" thick wall will not fail but a 1/2" diameter pipe with a 1/16" wall will be history. Thus all beams have what is called the "cross section moment of inertia" ("I"), the number which defines the effect of the physical geometry of the beam. For common structural shapes like standard pipe "I'" can be looked up in published tables which makes checking pipe antenna masts a fairly simple process. For more complex structures like tower sections with three legs and cross bracing ya got a real rat's nest of calculations to deal with.
>
The third factor which enters into the analysis is the orientation of the load with repect to the orientation of the geometry of the beam. A 2x4 for instance will take a much higher load if pulled in one direction than in the other. The number which defines this effect is "c", the distance from the "neutral axis" of the geometry to the "extreme fiber" in inches. In the case of a 3" diameter pipe the neutral axis is simply the axial centerline of the pipe and c=1.50 inches. Once again, determining "c" is another rat's nest when dealing with more complex structures.
>
Roll all these factors together and plug the numbers into a very simple equation s=Mc/I and bingo you'll have the maximum stress in the tower or mast or whatever. Which in the case of a tower sticking up out of a concrete base always occurs at the surface of the concrete. If the result is anywhere near 30,000 Lb. per square inch for a steel structure you better go back to the drawing board and either get rid of some load or beef up the cross section geometry.
>
Reality is much more complex than my simplistic rant on the subject but the basic relationships are there. There's a whole stack of additional factors which also need to be cranked into a realistic analysis. A secondary load called the "shear stress", the non-uniform but distributed wind load on the tower itself in addition to the point loads created by the antennas and mast, stress concentration factors, corrosion allowances, the design safety factor, determination of the failure mode, tension or compression buckling of one of the legs, etc.
>
Which in a nutshell is why you put towers up by the book and don't get stupid and try to outguess the pros who designed the tower by pushing their published loading and installation envelopes.
>
>

> Note that the 4x4x4ft concrete base didn't budge.

>
There are two kinds of bases. The base for a guyed tower is there simply to keep the tower from sinking into the ground because the guys take the horizontal loads, the base of the tower is loaded in compression, not in bending except in specific odd circumstances like not enough guying. It might be noted that the guys only take out the horizontal load on the tower. They *add* vertical load to the tower. Trig 101. Therefore the vertical load on the base and the tower legs is the dead weight of the whole shebang *plus* the downward component of the wind load on the guys. Given enough wind you can collapse a guyed tower and/or the base straight

into the ground. Which is why once again you pay attention to the book and don't anchor the guys too close to the tower.
>
In the case of a freestander the primary function of the (much larger) base is to act as a sort of counterweight which balances out the wind load at the tipover pivot point. Gets into soil mechanics, etc. In all cases more concrete deeper is always better.
>

>

Lots of the old BC AM radios had that frequency marked at the top of the dial. That was the station-to-car frequency, of course. The CW net operated behind the scenes, handling the interdepartmental traffic both near and far, and lots of relaying took place.
When I hired on to the Missouri Highway Patrol in early '65 to work in a district HQ, we still had all the CW gear in place and functional, although a newly installed Model 28ASR TTY now handled the traffic that had long been handled by CW. The Chief Op fired up the Collins autotune xmtr and tested it ever couple weeks with the state HQ station, which itself still handled lots of CW traffic routinely, since Missouri was a primary relay station for traffic headed both east and west and many other departments had not yet made the transistion to wireline TTY. I was tested on my CW skills as a part of my employment testing but was never assigned where it was in current use.
After a year or so of proving the viability of the wireline TTY circuit, the CW transmitter and its antenna were removed, but we retained the console mounted receivers (two National RCL's) and the receive antennas (dipoles on 50 ft utility poles out back). We still used the receivers to check time signals from WWV. (And on boring late night shifts when things were quiet, some of us were known to tune in a ham CW band to help while away some of the slow hours <g>).
The upright Collins transmitter (can't remember the model number but it ran an 813 tube in the autotuned final) stood tall behind the dispatch console and fed a longwire which came right into the radio room through a insulated feedthrough directly to the top of the transmitter. Outside the radio room, the longwire sloped up to an attach point on the side of the 350 ft freestanding tower.
The HQ station in the state capitol ran two large Wilcox transmitters which used 750TH tubes in the finals and used several variations of Hammarlund receivers with dipole antennas. I was a part of the crew that removed all the CW equipment and antennas from that station in 1976. At the time it never occured to me to note how the old CW net came to a close, who was the last to use CW, and all that. Now I wish I had payed more attention.

Ed Hare, W1RFI wrote:
"Suffice it to say that at great distance, the signal reflected off a mirror is at the same level as the light bulb and the level of the signal reflected off the mirror does not appear less bright than the bulb if the distance between the bulb and the mirror is changed, as long as the observation point is >> the distance between the bulb and the mirror."

Approximately true if the bulb is close to the mirror.

It`s true that the energy reflected from a perfect reflection point is the same energy that strikes the point. There is no loss.

But, when the source is far away from the reflection point, the image in the reflector is small. Little energy arrives at a reflector to be reflected. The combined energies from the radiator and reflector are mainly those of the radiator.

Something different happens when the reflector is at great distance from the radiator. The paths from the direct and reflected rays can be about the same length as happens at the grazing point on a microwave path. Depending on phasing, the two rays can combine to produce as much as a 6 db gain or a complete cancellation. The reflection is weak, but the direct ray is just as weak.

When the reflection point is close to the radiator but not close enough for the reflection to be nearly as strong as the direct ray, the combination of the two sources won`t be so dramatic. Nearly all the energy will come from the direct ray.

I just tried an experiment with a flashlight and a mirror which was inconclusive. The light reflected from the mirror was stronger with the flashlight closer to the mirror, but the total pathlength was changing considerably. The wavelength is very short indeed.

Best regards, Richard Harrison, KB5WZI

2279. Cushcraft warning

Hello to all,

First let me say that up until now I've been a happy camper
using Cushcraft products. However, I've just learned something
that may be of interest to anyone considering purchasing a
new Cushcraft antenna.

I recently bought an R-8 vertical. It was just damaged by
lightning and I e-mailed Cushcraft tech support regarding
parts availability....the answer was 2 sentences that suggested
I buy a new antenna and try to collect on insurance. Needless
to say, I was not happy with that so I wrote a letter to the
Cushcraft manager of amateur products. This gentleman was kind
enough to telephone me today. Essentially, the conversation
focused on the fact that the parts I needed would be so expensive
as to make buying a new antenna more practical. However, one
interesting fact did come to light. Parts for the R-8 vertical
had not been "priced" yet and were thus unavailable. Further,
Cushcraft does not "price" replacement parts until the product
has been out for 9 to 12 months. I'd suggest you keep this
in mind....if you drop your new R-8 or new whatever, you may
not be able to get parts for it for up to a year!!

thanks & 73,
Phil

>>
>> Thanks, Pete KA0TZK

With elevated verticals it helps to use the balun. You should use 1:1 (50:50 ohm) for vertical with few sloping radials (around 45 deg), which typically produced 50 ohm impedance. It prevents radiation from coax and reduces TVI caused proximity of RF fields from the coax.
If you have current meter, you could see the difference in suppressing the radiation from the coax. It helps tuning and the pattern too.

There have been several magazine articles on just what you are asking. How to build your own 6 meter cavities. Try doing a search on the web and try to locate them. I have the info around here someplace. Only problem is my file system leaves much to be desired.

You might do better in trying to locate some of the paging service companies where you live. Many of them have taken their low band systems off the air. As such they should have a number of the large low band (5 to 6 foot long) cavities around someplace.

When did they start this? I was a radio jockey (31V/31K)in the Army for 3
(87 - 90) years and never heard of Q or Z signs untill I got into ham. I
was operating in Batallion and Division TOCs as well as with field units and
retrans stations. We often used Lima Charlie (loud and clear) to respond to
signal strength queries and sometimes this was perverted into Lickin'
Chicken but that was the extent of any abreviations and no form of the Q or
Z or any other signs was used. In fact the rule was to always use plain
english and be as understandable as possible. If anything needed to be sent
"non standard" to help hide its meaning it was to be encoded using the
proper encryption and authentication for the day. No exceptions. Other
than that the encryption hardware took care of security.

So......I dont think there is

Jim, AC6XG wrote:
"I`ll bet the flashlight would be even brighter were you to hold it
right up to your eye."

I`d bet with you on that. Every experiment with a flashlight involves
the very far field.

The behavior of an antenna and the ground under it is declared to be for
practical purposes exactly the same as it would be in cooperation
between an antenna and its image in the ground, with the ground removed.

Coupling between parallel antennas decreases as the antennas are moved
apart.

Parallel elements used as parasitic directors or reflectors in a
2-element beam are usually spaced no more than 1/4-wavelength from the
driven element so that they receive enough energy to be effective. When
a director`s spacing is increased from 0.2 wavelength to 0.4 wavelength,
the power gain drops by 3 db or more. Doubling the separation halves the
power gain.

raising the horizontal dipole above ground must induce less current in
the ground and thus reduce lobe amplitude and null depth, just as
increased element separation would in a parasitic array which had no
affiliation with the ground.

Jim Bromley, K7JEB wrote:
"What the hell was this thread originally about anyway?"

Actually, a questioner asked the dimensions for a 10-meter rhombic. I was foolish enough to supply the dimensions.

Someone else opined that the size was excessive, how could he fit it on his lot? I replied to scale it down by a factor of 100, but to leave it up at 60 feet to get the free space gain of 11 dbd. Roy then opined that was wrong. The free space gain was not to be expected.

There's information on my web site... hey, you're already there ahead of
me!

It doesn't specifically mention your proposal about putting the 2m yagi
between two 70cm beams, but I think you'll now see it is a bad idea.

> 'Doc

1. You don't need a balun, strictly speaking, because both sides
(antenna and coax) are unbalanced. However, you *do* need a feedline
choke to keep surface currents from flowing onto the coax and down into
the shack. The type of antenna you're using is one of the worst for that
problem.

Exactly the same feedline choke could also be used as a 1:1 "current
balun" in a balanced/unbalanced transition. It can be as simple as a
flat coil of the coax that you're using already. Details are in the ARRL
Antenna Handbook and probably the main Handbook too.

2. I have no idea why Doc says that baluns do not stop RFI/TVI.
Thousands of people have proved that they do.

If the RFI/TVI wasn't going to happen anyway, a feedline choke can still
be useful in reducing RF noise pickup. At the very least, you'll have
the satisfaction of knowing that your feedline isn't behaving as part of
your antenna.

2304. Any Ideas?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-14 00:00:00 UTC
From: David Ackrill <Nospam@thanks.com>
Message-ID: <3a112440$1_2@news2.vip.uk.com>
Source record: 176537

I'm spending some time staying in hotels, and have started to take some Amateur gear away with me.

This week I've come up against a few problems though.

I'm in a ground floor room in a hotel in the middle of London where, presumably for security reasons, the window wont open. The window is also double glazed, so I cant even use the old trick of a couple of squares of tin foil each side of the glass as a way of capacitively coupling a wire through the window.

I've looked at trying to work a wire through between the window and the frame (although the window is locked, and there's no key issued to me to open it) but its a modern, double glazed unit with a tight seal. Great for avoiding drafts, and so that the air-conditioning works, but not for getting any wire through.

There are no other holes available from within the room to the outside world either. There may well be ventilation bricks, but not available within the room, as I say.

I've also tried using small verticals inside the room, with very poor results, not surprisingly, and a random wire across the room loaded via an Antenna System Tuning Unit (ASTU), again with poor results. Even on receive these did not perform very well last night.

I suppose that I could ask for the window to be opened for me but, although I have nothing to hide, obviously this is going to need a fairly long and involved explanation of Amateur Radio, antennas and why they need to be run outside and as high as possible.....

I could always give up on this week, and hope that I get a none ground floor room with a window that opens next week. HI!

Oh, and sitting out in the car is out of the question as well, it's getting colder at nights, and I really *don't* want to be sat in the car in the middle of London at night. Especially as my preferred mode of operation is CW. I can quite see why people give strange looks to people using a Morse code key in a car. Fortunately, though, I do use an Iambic Key and not a 'pump handle'. ;-)

Thanks - Dave (G0DJA)

Sheet metal screws (assuming stainless) won't make any difference in performance, but why would you do it? The clamps supply sufficient pressure to keep tubes secure and if you want to retune or disassemble the antenna, the burrs caused by the screws might make it very difficult. If you are having problems with the antenna and think the screws will solve it, think again. I had an R 8000 which after a mind numbing season of problems, fixed it by cutting it up, throwing away the traps and assembled a 20 meter monopole with the pieces. Good luck.

Hi Ed--

The only thing you missed is the problem of going from an unbalanced line to a balanced antenna. The outer surface of the coax will "think" it is a third wire connected in parallel with one side of the dipole (has little to do with matching, wire angle, or antenna pattern). The outer surface of the shield is just a big fat added wire connected directly in parallel with the antenna leg. If you're lucky and it's electrical length happens to present a high impedance compared to the (approximately) 25-ohm impedance presented by the resonant leg, you many never notice a problem--it won't "rob" much power and carry it back down to your shack. If you're not lucky, then it will give you some "in your face" RF problems in the shack!

A RF choke or balun at the feedpoint "breaks" this path with a high-impedance barrier against the flow of RF current. If you also add some ferrites or coil some coax near the rig, this adds a second checkpoint against residual RF current that may be picked up by induction.

Hope that helps.

Hello Dave:

You didnt mention what frequency you were trying to operate on, so I'll assume that the operating frequency is >28Mhz. Is this is true you may want to construct a folding wire loop antenna that can be easily taped to the pane glass window. The antenna itself will be very directional however depending on the room location, will probably be better than an "Rubber Duck" antenna.

Good luck and 73

Thanks for the suggestion Paul.

I should have been more specific about the frequency to be used.

The location of the room, as I say, ground floor, middle of a large city, is not very good for VHF. Though, as an aside, I do have a vertical for 2M/70cm which gets the local repeaters. More than that, it's a case of 1. Lack of VHF/UHF activity in the UK (even in London) and 2. A poor VHF/UHF location as well. I did try some APRS on VHF last night, but nothing heard on 144.800MHz (the designated Unconnected Nets/APRS frequency in the UK). I have tried loops made of tinfoil, with the middle cut out, but they don't stand up to much moving from one place to another, and wire loops are OK, but we are back to the poor location, plus the computer hash on the VHF bands. As well as the hotels computers, and other guests computers, there are the computers in the restaurants, offices and the banks. Plus the automatic bank teller machines, the fluorescent lights and the passing taxis and Police/Ambulance/Fire brigade vehicles to contend with. Not a place to try any 'serious' VHF operating........

No, I was trying to use H.F.. Working on the idea that I might work 'someone' (anyone!) on the H.F. bands. Hence the endfed wire (about 10 metres long) with a counterpoise. I have a much longer piece of wire, but I can't get it through the window. Which brings us in a circle to my original problem. HI. ;-)

I did hear a couple of stations on 40M, 30M and 20M. But these were very local European and Scandinavians and, I guess, were some of the higher power stations, as even 40M was very quiet. Not a 'normal' situation in Europe at night.......

80M can be good, for inter UK, but the problem there is that the 10 metres of wire is just long enough to go across the room. Any longer, and it would need to double back, which may cause signal cancelling on some frequencies, of course. It's also an inverted L shape, with the vertical part only some 1.5 to 2 metres (5 or 6) feet high.

The verticals I referred to were a 40M partly helical wound 'mobile' antenna and a converted 11M helically wound 'mobile' antenna. The 11M one being

modified by taking the small adjusting rod out of the top, and replacing it with a much longer whip. This was cut for the 20M band. It has worked well on the car. The problems with both of them in the hotel, of course, are that they are inside the building, and are not fed against a particularly good ground (though I could cut up the counterpoise and make a better RF ground, I guess).

I'll have a go again tonight, when I get back to the hotel, and see if I can actually work one or other of the stations which I can, at least, hear. Although, I'm still of the opinion that I'd really need to get the antenna outside the room, at least.

Cheers - Dave (G0DJA)

To save me having to wade through pages of unrelated sites after doing a web search for 'CIA', does any one have a URL that would take me to the specs and information on this unit please? ;-)

Also, my opinion of AEA is tainted by my dislike of their TNCs, if this is the same company that made the 'PK' range of units? Plus, their 2 metre band vertical, that looked like a knights lance, didn't seem to catch on, well, this side of the Pond anyway.....

My two-pennies worth on the MFJ units, I had one of the ones that went up to VHF, but not one of the latest that goes up to UHF. The only reason I don't have it now is that it was stolen, whilst in 'safe keeping' with some other gear, from a hotel in London a couple of years ago. They eventually paid up for the lost kit, but I've not yet got around to replacing the antenna analyser.

As soon as I get chance, I'm going to get another analyser, probably the MFJ259B, but maybe this CIA-HF, if they are sold in the UK.....

I'm trying to locate some data on how close my yagi's can be placed next to eachother without greatly effecting the others on the mast?

I have a:

5 ele 6m beam with about a 12' boom.
a Long Boom K1FO 2m yagi (12 ele I think)
a Long Boom K1FO 70cm yagi (22 ele?)

Anyway...I'm just trying to find a guideline for how close they can be on the vertical mast....they will all be mounted Horizontally....on a Vertical mast.

I was considering adding a second 70cm and phasing them together....and wondering how I should configure them all to get this done...I'm not sure I have enough mast currently to do this.

What are some thoughts on distances from each yagi to the next....(without the phased extra 70cm beam)?

The 6m will be on the bottom then the 2m and then the 70cm. I was thinking about having it go like 6m, 70cm (lower phased), 2m, 70cm (upper phased)

What do you folks think....maybe you can point me to some good sources on this as well....I've been out of the hobby about 6 years, and most of this has left my brain....(ooppps).

Roy Lewallen wrote:
"But again, the image antenna doesn`t depend on mutual coupling for its current, we impose its current. After all, we conjured the image antenna, so we can conjure the current just as handily."

Faraday showed the voltage induced in a conductor is proportional to the rate of change of a quantity of magnetic flux which links it.

Ampere showed that current creates a magnetic field. If current is changing, so is the magnetic field which induces a voltage, and this creates a changing electric field.

So, an alternating current produces an alternating magnetic field and an alternating electric field in the neighborhood of the conductor.

There may be no other conductor in the neighborhood of our current carrying conductor but current can flow in a void. This current is not conduction current, but it is called displacement current. Displacement current allows a-c to flow through a capactor`s dielectric, which can be air or a vacuum. Displacement current is proportional to the dielectric strain caused by an electric field. In a capacitance, the displacement current must equal the conduction current in the wires.

J.C. Maxwell proposed that a magnetic field would be caused by a displacement current, just as a magnetic field is caused by a conduction current. Maxwell produced an equation quantifying the electric field that would be caused by a changing magnetic field. He also produced another equation quantifying the magnetic field that would be produced by a changing electric electric field.

An alternating current in a wire produces an alternating magnetic field in the space around the wire. This creates an alternating electric field which causes a displacement current in space which produces yet another alternating magnetic field surrounding the displcement current. Each alternation exceeds the distance from the wire of the previous alternation and this can go on forever.

But, as the radiation spreads farther from the wire, the same amount of energy is spread more thinly over a larger area. The amount that can be captured by a distant conductor depends on how close it is to the source.

Roy may conjure an image antenna, but he can`t conjure reflected radiation which produces an actual interference pattern with radiation from an actual antenna. Radiation from the ground reflection requires actual current tnduced in the ground which in turn becomes another actual source of radiation. Strong current makes strong radiation. Weak

current makes weak radiation. (from earth)

Strong direct radiation is little affected by a weak reflection from the ground.

The height of an antenna above ground is significant to the strength of the reflection from the ground.

Best regards, Richard Harrison, KB5WZI

Source record: 176552

Terman says on page 883 of "Electronic and Radio Engineering": "For purposes of calculation, it is convenient to consider that the reflected wave is generated, not by reflection, but rather by an "image" antenna located below the surface of the ground.--- When the earth can be considered as having a reflection coefficient of approximately unity, an assumption that is very commonly made, the currents in the corresponding parts of the actual and image antennas (i.e., in parts lying on the same vertical line and at the same distance from the earth`s surface) are of the same magnitude."

That is the argument some are making for an antenna at 180 wavelengths above ground.

On page 836, Terman says: "Consider the antenna that is far enough from ground that the total power reflected by a given set of antenna currents is independent of the presence or absence of ground.--- This condition corresponds to an antenna height great enough to make the mutual impedance between the antenna and its image small."

This is exactly the proposition I`ve been arguing from the start of this thread.

Best regards, Richard Harrison, KB5WZI

I will let Roy address this one. Suffice it to say that at a great distance, the signal reflected off of a mirror is at the same level as the light bulb and the level of the signal reflected off the mirror does not appear less bright than the bulb if the distance between the bulb and the mirror is changed, as long as the observation point is >> the distance between the bulb and the mirror...

> Strong direct radiation is little affected by a weak reflection from the
> ground.

> The height of an antenna above ground is significant to the strength of
> the reflection from the ground.

Yes, it is, but that is the very reason that one must be in the far field to make any reasonable calculations or measurments.

Let's put an imaginary half-wave dipole 100 wavelengths above ground. Now, go to a point 1wavelengths above the antenna and make a measurment or do a calculation. Whoops -- at this point, the value of the fields are determined primarily by the antenna itself. If the direct wave creates a field of 1 V/m at a point 1 wavelength above the antenna, the influence of the reflected wave will be negligible. One is not equidistant from the energy radiated by the antenna and the energy reflected from the earth. If, at this point, the signals are out of phase, they are not of equal amplitudes, so there will be no cancellation of the signal at that point. I believe that this is how you are thinking of antennas. So far so good.

Now, let's go to a point 1E+6 wavelengths above the antenna. Okay, at this point, the direct signal has traveled 1E+6 wavelenghts and the reflected signal has traveled 1.01E+6 wavelengths -- they are at virtually the same intensity. If the fields are in phase at that point, they will add (+6 dB); if they are out of phase, they will cancel. If the antenna is at a height that is an integral wavelength above ground, at any distant point above the antenna, the signals will be out of phase and at approximately the same amplitude, so they will cancel.

At points above the antenna that are not distant, the signals are still out of phase, but will not be at equal amplitude. Let's look at a point that is

100 wavelengths above the antenna. The direct signal has traveled 100 wavelengths; the reflected signal has traveled 200 wavelengths; they are out of phase alright, but not of equal amplitude. In fact, the direct signal is 20log(200/100) stronger than the reflected signal -- 6 dB stronger. There will be some cancellation, it will not be significant.

Now, lets go 200 wavelengths away. At this point, the direct signal is 3.5 dB stronger than the reflected. At 1000 wavelengths away, the difference is 0.8 dB. Etc. At what point do you need to be to measure the gain of the antenna? At what point would you have to be to measure a 10 dB null in the far-field pattern caused by reflection off of an imperfect ground? I would imagine that the direct and fields were of equal amplitude within less than a dB, one would have a reasonable accuracy for a 10 dB null. At what point would you have to be to measure a 60 dB null in the pattern?

Yes, you can make a measurement at any point and have a measurement valid for that point, but if you are trying to measure the pattern of an antenna, and want a far-field pattern that is valid for any distance (the basic definition of far field), one must be very far from the antenna to measure deep nulls in the pattern caused by the ground reflection. And, very far from the antenna, the depth of those nulls is not influenced by the height of the antenna above ground.

73,
Ed Hare, W1RFI

.

Thus, even at very distant points, the pattern of an antenna over ground is determined by the direct signal from the antenna and the signal reflected off of earth, even if that antenna is very high, presuming that one is in the far-field of the radiating system.

Best regards, Richard Harrison, KB5WZI

BALUN stands for BAlanced to UNbalanced. Coax is unbalanced, A groundplane is unbalanced- .So you do not need a balun. Since a vertical has a theoretical feed Z of 37 Ohms- it will present a VSWR of (50/37)-1.4:1. A 4:1 would make the Z= 4X37=148 Ohms yielding a VSWR of (148/50=3:1. If anything you might want a 1.4:1 UNUN (Unbalance to UNbalanced). But the difference in signal strength between 1:1 and 2:1 is virtually unmeasurable.

Get a copy of the ARRL Handbook- this will answer all of your questions.

You can still have common mode currents with a perfect match. The match
has no bearing. You would still want a 1:1 ratio balun or a choke to
reduce feedline radiation. Also 213 and rg8 basically the same thing
with the same electrical specs. Just 213 is direct buryable and has a
non contaminating jacket.

#1 The best thing to do is have your antenna support "mast or tower" as
well grounded as possible. You want to direct the strike to ground at
that point with as little resistance as possible. This is 85% of the
whole game.
Myself, I use no ground in the shack except for the plug in safety
grounds. When bad weather is around I totally unhook all the antennas
and ground them out outside the window to the ground which is tied
together with the "mast" ground. I have no ground in the shack which is
connected to this outside ground. Myself, I prefer to be isolated from
it. If you use a ground inside, you must tie all connections together in
a star pattern,which is connected to the ground bulkhead. Don't use a
bus. If left connected, you will need to suppresss every line coming in
with gas tube suppressors"includes power, phone line". I don't do this,
so I just ground out outside. Accomplishes about the same thing, except
it's a pain in the rear to worry about. I took a direct strike on the
mast with no problems with my setup. And was sitting 15 ft away from the
mast when it hit. As one said, there is a ton of lightning info in the
deja news, and you also might want to look at the polyphaser web site.

Hi Ed,

Nice discourse. I understand that it helps illustrate the point here,
but in practice how reasonable is it to assume that 100% of the incident
RF enery is reflected? What is a practicable reflection coefficient at
HF for example?

This very much depends on soil type, and the grazing angle of the
reflection, etc. The FCC's OET Bulletin 65, as based on some estimates by
EPA, suggests that an antenna would show about 4 dB of ground gain. If
true, this would mean that the reflected field had a voltage or current of
about 60% of the incidental field, which, if adding in phase, would give a
voltage of 1.6 times the voltage that would exist in free space at that
particular point, thus, if in far-field conditions, a power density 4 dB
stronger than the antenna would show in free space. (This is offset by the
fact that the reflections cancel at other angles.)

If one looks at the EZNEC-calculated antenna pattens of a half-wave dipole
over ground, if the dipole is 1 wavelength above imperfect earth of
"average" conductivity and dielectric constant, the null straight up is -12
dB and the null at 30 degrees is about -17 dB. I lack the skills and
knowledge to calculate the phase of the reflection, so I cannot tell you
what percentage of the signal actually gets reflected, but if the phase
were -180 degrees from the incidental, the -12 dB null would be caused by
reflected field with a voltage of about 75% of the incidental field.

I am sure there are some folks here who can express this much better than I,
and certainly more completely, so I will kick back and learn a bit from what
they offer. :-)

Richard Harrison posted (in part):

> On page 836, Terman says: "Consider the antenna that is far enough from
> ground that the total power reflected by a given set of antenna currents
> is independent of the presence or absence of ground.--- This condition
> corresponds to an antenna height great enough to make the mutual
> impedance between the antenna and its image small."
>
> This is exactly the proposition I`ve been arguing from the start of this
> thread.

Just to quibble with this a bit, the above quote is on page 886, not 836.

The complete quote is:

"Consider the antenna that is far enough from
ground that the total power reflected by a given
set of antenna currents is independent of the
presence or absence of ground. Then a ground
reflection that reinforces the main lobe will
double the field strength of the main lobe and
so will increase directive gain of the antenna
by a factor of 4.* This condition corresponds
to an antenna height great enough to make the
mutual impedance between the antenna and its
image small."

* "This assumes that the free-space directional
pattern of the transmitting antenna has a
maximum in the direction in which the ground
reflected wave reinforces the direct radiation."

So the condition Terman is writing about is still where the
direct and reflected waves add vectorially. Otherwise, how
could one get the 4X increase in directive gain? But also
noted is the statement concerning the negligible effect of the
mutual impedance between the radiator and ground. I contend
that the the 2D^2/lambda criterion (where D is the distance
to the centroid of the radiator/image combination) still holds
for *accurate* far-field pattern measurements because of the
vectorial addition taking place between the direct and reflected
waves, even though there is negligible mutual impedance between
the direct radiator and any ground image.

The point lies in that adjective *accurate*. The difference
between measuring a pattern inside and outside the criterion is

just a slight shifting of the pattern nulls for most practical
cases.

What the hell was this thread originally about, anyway???

Dear Group: When I was at Ohio State I made the acquaintance of the
head of the communications department for the Highway Patrol - sure
wish that I could remember his call. He took me out into the country
to the HF site. They had long, high dipoles. The CW transceivers
(rack mounted inside of a cement building) were run by a microwave
link from the downtown HQ - as the boss said "a mighty long IF
strip."
I kept a Model 15 TTY machine running in my little appartment
(covered by a box to make it more quiet). That was "high tec."
What changes I too have seen.

Hi All,

Richard's logic seems to consist of equal parts experience and book
references with the hedge toward experience.

In regard to the statement above, experience would have us leave off
with the "perfect" ground scenario, especially in the microwaves where
both the experience and book references would converge.

The variation in terrain, even in Kansas, at microwaves would
guarantee a lack of coherent reflection to allow for any accurate
development of a 10 (much less 60) dB null. In other words, the
variation of terrain height (we are talking inches now) from the
perspective of the radiator's wavelength guarantees some nulls would
be filled and some lobes to be leveled - on average.

If we were to revisit this at the original 10M Subject line, then that
variation in terrain would have to be substantial (now meters instead
of inches) to blur these lobes and nulls.

Q signs are just abbreviated ways to say things to make conversations take up less air time. Amateurs use Q signs and the military uses Z signs first and then Q if no Z sign is available. The military rule is to never use plain language when a Z or Q sign can be used. So......I dont think there is a meaning for QSO other than a quick way to say "Can you communicate with _____ direct?" or to designated a direct communication. But, I'm often wrong. Mike-KA7CGI

Source record: 176524

George, perhaps 'connection' is a poor choice of word. It is more applicable to two well-defined conductors which join at a single point.

Nevertheless, the purpose of a radial wire is to transfer the antenna current to the soil with the lowest possible 'contact' resistance. Note that the required direction of current in the soil is the same as in the radial. The soil resistance is in parallel with the wire resistance and inductance - not at right angles to it.

Most of the soil resistance in the circuit is due to the thin layer of soil which is very close to the radial wire. The current has to cross this thin innermost layer obliquely to get into the soil. As the distance from the wire increases the cross-sectional area of soil in a layer of the same thickness increases and so the resistance of a layer decreases in inverse proportion to its radial distance from the wire.

The total resistance of all the layers in parallel up to a given radial distance from the wire decreases rapidly. Eventually, of course, the resistance is less than that of the copper wire. At not too great a distance from the wire the resistance of the soil is certainly less than the wire's inductive reactance and most of the current then flows in the soil. At some axial distance along the wire there is so little current in the wire it becomes redundant. The length at which a radial wire becomes redundant is often overestimated.

Returning to the radial dimensions, it is not too difficult to see that the wire diameter is of consequence. The greater the wire diameter the lower the resistance of the soil in the innermost layer. For the process described above to get going it is necessary only for the burial depth of the wire to be very much greater than wire diameter. The previously mentioned depth of 6" foots the bill. I prefer 10" - it allows back garden cultivation to be carried on down to a spade depth without affecting the DX.

Insulated radials have no more loss at HF than the bare wire variety. That's because insulating materials such as enamel and pvc have a very good dissipation factor. Furthermore, the diameter over the insulation is greater than that of the bare wire and so the innermost layer of soil has a lower

resistance than with the bare wire.

Looking into the electrode system we end up, therefore, with a similar loss resistance but with a capacitance in series. The capacitance is that of a coaxial structure with inner and outer diameters and is calculable. Not that this matters very much - it is tuned out by the tuner simultaneously with the antenna reactance from which it is indistinguishable.

The foregoing is a simplification. Radials are transmission lines with lossy dielectrics and have such nuisances as Zo, propagation velocities, etc.

Nutshell/thumbnail, the weight of all that ice, probably a lot more
than the tower itself, moving in the same direction as the wind gust
that broke it, just proved too much load, and at the fulcrum, at the
base, it gave way. No way I could have forseen that, but I DID plan it
to be far enough away from the house to miss it if it did come down.
Except for the raingutter, I was right on that score.

> In the case of a freestander the primary function of the (much larger) base is to
> act as a sort of counterweight which balances out the wind load at the tipover

Outfit I used to work for had a 350 footer, wide base freestanding,
that was hit by a tornado on the other end of the state. For a long time
I kept a photo of the hunk of concrete that one leg pulled out of the
ground. Helluva a chunk it was, too. MANY cubic yards. Then it laid the
tower across US36.

> >
> > While such weather events are rare in this part of the world, I am

>
> >
> You got bit too hard. Lotsa freestanders out there which can take the loads.
> Lookit all the freestanding cell phone poles. Ya just don't push the numbers.
> >

After all my towering experiences, it just seems natural to ask- just
how much are these installations professionally overengineered? I think
its a given that any vendor or engineer would make absolutely,
positively sure that no one ever could, for any concievable reason, be
able to point the finger backward after any tower came down, so that
naturally means "overdone". By how much?

> Hey, Dick - Put another set of guys on that tower willya?
>

I would've bet that was coming <BSEG>. Point is, the darn thing has
stood there 15 years, through some hellacious Midwestern winds, without
flinching. And after previously closely watching the freestander that

the iceload took down, I really believe *it* would still be there
without the ice storm. So really, What's the deal?
In fact, if I read your detailed info right, another set of guys would
add more vertical compression. I know that they would also stabilize the
middle and forestall twisting - but thats why I put them at 50 ft
instead of the top (60), and I haven't detected anything that looks like
a deficiency or any hint of problem. A middle set wouldn't keep it up if
one of the top guys failed. Explain for us all, pse. Us backyard
injuneers want to know.

BTW I did a bit of reading back when working about how towers fail in
earthquakes, since I had New Madrid in my area of responsibility. Turns
out that the freestanders fare better than guyed types, which suffer
slackening in one set of guys as the first earthquake wave arrives, and
the opposite guys, still tight, pull the beast down. The freestander
just sways and stays put....some of the time, anyway.

tnx, Brian

> expert opinions out there ? Thanks Brian K3USC
>
Hi Brian,
I currently have a 200' dipole which I can tune on all bands from 160m through 10m. With this length, it is shorter than a half-wave on 160m, but longer than a half-wave on 80m and all other bands. I picked 200' mostly because it fit my lot. I haven't done the full-blown analysis but I suspect (actually hope) that this length improves the chances for impedance matching. On 160m, the 200' length should result in a relatively small capacitive reactance and a relatively large resistance so that my tuner is able to find an impedance match. On 80m, this same length should also result in a relatively small inductive reactance (a half-wave on 160m results in about a full-wave and potentially very high impedance on 80m). This is all subjective, but if you put up a 180' dipole, it should work. 73,
Bill N3WK

Yes, I have a recent copy of the ARRL Antenna book which mentions that
the grounds must be connected for safety reasons.

>Rick did a good
>job dealing with the RF issues, I'll just stick with safety...

Thanks. The safety issue is particularly what I wanted to know more
about.

>However, the way to accomplish that is *not* to pick up a 'ground' at an outlet
>that happens to be nearby the coax' entrance to the building. The safety ground
>available there is designed to provide a path to ensure (among other things) that

That helps already -- I can read more about this in the local
library's copy of the NEC.

>the ground connection from an "antenna discharge unit" :
>

>250-92(b)
>d. The metallic power service raceway
>e. The service equipment enclosure, or
>f. The grounding electrode conductor or the grounding electrode conductor metal
>enclosures; or

Unfortunately, the service entrance of the building (and the location
of the main grounding rod) is 110' away on the far side of the house,
so I think that shoots 1a. The pipes are PVC, so 1b is out. There is
a ground that's only about 40' away on a subpanel in the garage, but a

route to it would be somewhat difficult, since I'd have to go all the
way around the garage.

>(h) Size. The grounding conductor shall not be smaller than No. 10 copper, No. 8
>aluminum, or No. 17 copper-clad steel or bronze.

That's useful info, because the wiring to the outlet is only No. 12.
I was going to use solid No. 8 copper to bond to the ground rod.
Anything much bigger and I'm not sure I could bend it!

>So... your connection goes to a grounding electrode (your rod driven into the
>ground. You should interconnect it, and when you run the interconnection you need
>to make a straight run to the point you use (lots of folks use the service entrance
>enclosure and its associated ground connection). Normal house wiring doesn't use
>#10 sized ground conductors.

Yep. If I ran #10 wire all the way 'round the garage to from the
subpanel to the electrode, would there be any problem with that?

>In summary, connecting to the ground available in an outlet won't accomplish what
>you want. And. being a GFI outlet, there's a good chance that if any stray RF is
>on the outside of your coax, you'll trip the GFI and turn off anything attached to
>that outlet.

I figured that it was inadequate but I needed more specific info to
figure out what would make it adequate. You've given me just what I
needed, I think.

>Might be interesting with Christmas lights plugged in there in the winter :-) ...

As long as the flashing red lights are decorative and not on an
ambulance or fire truck, I'll be of good cheer! Thanks for the help.

Yes, I'd read that but the materials I have here seem to have more
warning than practical help. I'm a relatively new ham (since 1998) so
maybe there is a resource I've overlooked. Is there a definitive
article like "How to Plan Your Grounding System" that's available
somewhere?

>To prevent what are called "common-mode RF currents" from returning to your
>shack, make sure you use a balun of some sort at the antenna's feedpoint
>(ferrite sleeves, coils of coax, or something), and also wrap a few coils of
>coax at the back of your rig and tape them up. If no RF current can come back
>down the outside of you feedline, the chassis RF potential on your rig should
>remain "cold" and you can then connect a wire to ground rods that will act as a
>DC ground without radiating RF. That's the condition you want to create.

The particular inverted V I'm installing is tuned to 80m and has,
according to the books, a characteristic impendence of 50 ohms in that
band. Since I'm using RG-213 (I think I mistakenly said RG-8 in my
message), it seems like that would be pretty much a perfect match and
no balun or choke would be required as long as I kept to that band on
that antenna. Have I missed anything?

>I also disconnect my
>feedlines and master power when I'm not using the station to avoid problems
>from thunderstorms or severe snow static.

I'm told that North Carolina, where I live, is the #3 state in the
nation for lightning damage. That's why I'm particularly interested
in getting the grounding system and lightning protection in place and
done correctly.

Thanks for the advice, Rick.

I have a 2000 Tahoe and had the same dilemma. My solution was an L bracket mounted between the hood and fender. There is sufficient clearance so as not to interfere with opening and closing the hood.You still have to drill three small holes on the inside of the fender but you'll never see them. Most ham stores carry these brackets and are available in NMO mounts.Not the best solution but it works pretty well and it's better than tearing up your new truck.

It doesn't seem to be all that widely known, but there was a Interstate Police HF Radiotelegraph Network in service from the thirties well into the 1970's that used the Z codes extensively. Prior to deregulation of telephone line rates the use of radiotelegraph systems was much more cost effective than rented wireline TTY, in times when public expenditures were much less liberal. So the HF police CW net persisted long after available technology would normally have replaced it.

I have a couple of APCO (Associated Police Communications Officers) handbooks from 1945 and 1951 which detail the network, its member stations and the systems and procedures used, including a listing of the Z codes.

Anyone who would like to read a first-person account given by one of the CW operators who worked at a station on that net can do so at:

Ed, if you want to read all you'll ever want to know on the subject of grounding and lightning, and how to deal with them, do a Dejanews search of the archives of this NG using the words "antenna, Lightning and Ground". You should be able to get enough good information to shed some light on a complex subject that at first doesn't seem like it should be one.

I agree. But, let me say, I have been a firm beliver in the application
of fractal geometry since Benoit Mandlebrot wrote the orginal book on it
while a scientist for IBM in (I think) 1984/85.

While I disagree with the tone an type of posts by Dr. Cohen I hope this
newsgroup does not write off this interesting application of fractals.

Are they better or worse than other antennas? I have no idea. But what ham
radio is all about is testing, experimenting, improving and let others know
about the results.

I for one say lets keep on hearing about these interesting developments, but
lets keeps it at a scientific level, without insults, threats, etc. from all
party's concerned.

I would hate for this newsgroup to translate its fustration with Dr. Cohen into
the belief that there is no merit in fractal technology. There may be, but
sometimes the most interesting advances come from such disruptive/different
viewpoints.

>
>that's why i like my DC grounded antennas or baluns

If the arc is corona, it won't matter if the element is dc grounded or not.

Corona comes from the charge gradient between earth and the area around the antenna.

SHAPE of the antenna, where the antenna doesn't have sharps points sticking up in the open, reduces corona by increasing distribution of charges along the surface of the antenna. In some cases, this can reduce noise during storms.

DC grounding prevents arcs internal to the feedline and antenna, not external. The main effect of lack of DC grounding is occasional "pops" as something in the matching system, feedline, or antenna breaks down.

Quads are quieter only for two reasons. They often don't have a sharp point sticking way out in space, instead having a long length of wire. They also generally have a lower impedance part of the antenna exposed to the strong electric fields where corona occurs. These effects reduce the amount of "rain or snow static".

Any antenna can be cured of the "DC ground" defect by adding a leak resistance or choke across the feedpoint. Curing corona requires only a change in height or shape.

>73,
>Ed Hare, W1RFI

I'm a bit late on this, but I hope someone pointed out that ground
losses as well as current reduction in the wire with distance limits
the useful gain of a Rhomic and other longwire arrays.

Gain peaks at about 3.3 to 4 WL per leg, and then actually falls off
in a Rhombic that is 1/3 it's leg length in height above earth. It's
pretty easy to get more gain from much smaller antennas, especially if
the longwire array is not high above earth compared to it's size.

Most of the gain figures in books ignore real world losses and effects
of earth, and greatly over estimate gain.

>unfortunately landlords are
>not always cooperative

Well, I can only guess, but if your landlord or superintendant is willing to allow your antenna on the fire escape which might be more visible than the roof, he might just let you put it on the roof, as long as you display to him you know what you're doing and can assure him it will be safer and would be less intrusive into the lives of other tennants (RFI, asthetics, etc.)

Good luck,

My aunt had an RCA console receiver that went up to about 18 Mc/s (as they said in those days). Shortly after the end of WW2 I started listening to the ham bands on it. I soon got tired of what I heard on the phone bands -- some things never change -- and I wanted to try to learn to copy code. I solved the BFO problem by putting an all-American 5-tuber on top of the RCA and tuning the little radio so that a harmonic of its local oscillator would beat against the CW signal I wanted to copy. The only trouble was that if I wanted to QSY I had to tune both receivers. Eventually I saved up enough money to buy a beat-up used Hallicrafters S20R and I said goodbye to the big old RCA (which was built about the same time as I was). Soon thereafter in 1949 I got my class B (what they used to call General class) ticket, and my Extra in 1955.

Jesper--

The R6000 won't work on the ground. It can't work on the ground because it isn't designed to work on the ground. The counterpoise rods have to be about 8-10 feet above the ground. Put it on a 10-foot pole, and unless it's broken or assembled incorrectly, it ought to work okay!
Of course, if it's set up 5-10 feet away from a house with aluminum siding or some similar scenario, then it will be de-tuned by all that metal.

Don't try to redesign unless you're extremely savvy about those things.

It's a bit difficult to carry on a discussion about anything when
one of the disputants threatens the others with lawsuits, and
links their posts with Nazi propaganda. If both sides don't agree
to disagree in good faith, then any discussion will eventually
deteriorate into childish chaos.

Attempts have been made, believe it or not, to investigate the
nature of fractal antennas by some contributors to this newsgroup.
You may want to look in dejanews to see how they were rewarded for
their efforts. Some of us would like to see more serious discussion
of all types of new antennas, but the future looks bleak in this regard
due to the infestation of trolls.

2361. 160/80 Dipole Parallel or Trap?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-15 00:00:00 UTC
From: Birken Vogt <vogt@oro.net>
Message-ID: <3A1328C5.1AA8C304@oro.net>
Source record: 176381

I have been considering an antenna for 160. I have been modeling different ones with EZNEC/Demo. I had been considering an inverted L but the nulls bug me and the gain doesn't seem that good, even though I can only get the dipole up about 50 feet. Then the idea struck me to do some kind of combination. I have a trap modeling program (called TRAPDIP) but EZNEC gives me very odd impedances and patterns on 80 off of center frequency which I have as 3.795. The parallel dipole solution seems better but I don't know how to construct it, what to use for spacers.

Any hints?

Hi Jim, All,

I love it when light is drug into the wave phenomenon of RF.

Having design many photometers, one of the principal pains in the *** was fresnel loss (mostly because I worked with pulsed systems). Like earlier debates of the mismatched source line and load, there is absolutely no such thing as a perfect absorber (load) and there is absolutly no such thing as a perfect transmitter (interface or lossless transmission line). The upshot of this all is in response to the last line quoted above. All interfaces reflect some power, even the best could qualify as quite bright in reflection depending upon the amount of light illuminating it.

As to being detectable to the eye. If there someway to correlate that light, or other wise reduce distracting illumination; some of the faintest of sources could be seen in reflection. 1 uW/mm^2 with a Lambertian field is very bright in a dark room. One would need only a 1 W bulb directed through an exquisitely transparent pane to see a red filament in reflection.

The eye is quite capable of coping with reducing that power several orders of magnitude and observing that reflection still being visible. The threshold of perception easily eclipses much of science's best equipment.

2377. How has Ham radio helped you?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-15 00:00:00 UTC
From: gcouger <gcouger@NoXSPAM.mercury.rfdata.net>
Message-ID: <4FsQ5.569$vn5.1965@newsfeed.slurp.net>
Source record: 176461

I am trustee for W5YJ the club station for Oklahoma State University. We find ourselves about out of student members as is happening more and more often. In looking for reasons for kids to get their ticket several of us got to talking about what ham radio had done for us. My son got he first job in Silicone Valley because the guy that was going to be his boss was a ham. The faculty adviser jumped two grades when he joined the navy. I found it helped me a lot in developing wireless computer links.

I would greatly appreciate short emails that give examples of how ham radio help you in you professional lives. Particularly recent grads. But stories from the old war horses on the group are welcome as well. The will be posted to a web the club web page temporally located at www.couger.com/W5YJ since the owner of the proper page has gone trucking and taken the passwords with him. It will find a proper home as soon a possible.

I know ham radio help in the professional world. The greater the effort in ham radio the greater the pay off in the real world. I want to show the kids that there is something that they can do that is not difficult, fun, a service to the community and valuable to their careers. We are facing a real crisis competing wiht the internet for the kids and even the old farts our local nets have dropped to 25 to 50% of what they were PN(Pre Net). The station started out as 5YJ and I don't want to see it die on my watch.

The pages and testimonials I put together will be available for all to use. And if anyone has any ideas on how to recruit new kids I am all ears.

I know this not the right group but it is the only one I follow any more.

Thanks
--
Gordon W5RED

>David, I was in a similar situation in a hotel room 10 years ago at Disney
>world. I used capacity coupling through the glass using about a square foot
of
>aluminum foil on both sides of the window

Thanks for the reply John,

I did consider this idea, as per my second post, but there were two problems
which I could see immediately;

1. I didn't bring too many tools, so making up the foil capacitor idea might
prove a challenge and;
2. The windows are double glazed, so the air gap, plus two sheets of glass,
will increase the capacitance quite a bit.....

I may pop by the supermarket on the way back to my hotel tonight for some
foil, and see if I can find a way of attaching my copper wire to the
aluminium foil.

As I used to be an engineer with one of the electricity utility companies, I
don't underestimate that problem.......

Cheers de Dave (G0DJA)

Bought an R-7000 a couple of years ago at Hamvention in Dayton. Never could
get it to tune. No help from Cushy on that one either. It still don't
work. Been laying up in the attic in the original box for a year now.
Never again will I buy one of their products, after buying many of them over
the years. Terrible customer service and equally terrible attitude when you
try to get an answer from them.

I'll be getting a longer antenna because my mobile rig also has 6 meters,
and I'm hoping the antenna gain will more than compensate for the lower
mount location. The fold-over feature solves the garage problem. Thanks
for the info.

Very nice posting, Ian. A 1:1 choke can be used as a balun or a unun
to reduce common-mode currents.

As they point out on the above-referenced page... parts are
still available for every Butternut antenna model they've
ever made! Their customer service is excellent. I've had
an HF-6V for over 15 years, and on the rare occasions that
I've needed parts or advice, they have been there for me.
Based on everyone else's experiences with Cushcraft, looks
like they'll never get any of my money.

Strictly the neighborhood patrol guys.
>
Off on an aside here the big advantage of that old system was that everybody could hear everybody, there were no municipal or jurisdictional borders on the radios, perps crossing municipal and county lines couldn't beat the radio, the next jurisdiction simply picked up the
pursuit, etc. As you know eventually they moved it all to separate departmental vhf freqs and
all of a sudden the only connections between departments were the dispatchers with telephones
which introduced a lot of time delays and frustration, etc. Went on for decades. In this sense
the old AM freqs were much better than the new-fangled vhf FM systems. Around here today everybody is now trunked to everybody else with 6 inch antennas and it's finally back to what
usta be a half century ago. I guess, I haven't paid any attention to it for years.

2393. Cushcraft R-6000 question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-15 00:00:00 UTC
From: jkristia@my-deja.com
Message-ID: <8uucm2bfh1@nnrp1.deja.com>
Source record: 176477

I have recently purchased a R-6000 from Cushcraft. The reason I decided to go for a vertical is that I only have 5x6 meters on my patio, and thats all the space I have available.

The antenna is placed directly on the ground, and it doesn't work at all. It is absolutely dead. The interesting think though is that if I connect the cable directly to the antenna instead of through the matching network, I have a fine (everything is relative, right !!) signal, but through the network and it is dead. So I blamed it on the network and returned it to Cushcraft for replacement. Yesterday I received a new network, and this time I was sure it was gonna work, but big big disappointment, dead dead dead.

Now my question is, shouldn't it be at least as good a signal as when the cable is connected directly to the antenna ?, and should it work (not good, but still work) when it is placed directly on the ground ?.

I will appreciate you answer.

Unlike a monopole, it doesn't require a wire ground for operation
because it is a full-wave loop. Of course, the better the ground
the better the performance. It was modeled over average ground
using EZNEC. In its favored directions, it has more gain than
a 1/4WL monopole with radials, a lower take off angle than a
dipole at the same height, and fits in the space of a G5RV.

I tried a year or two ago to get parts or even information about the matching box at the bottom of an R7 Cushcraft. Since I bought it used, it would never work on other than the two highest bands. Couldn't even get an SWR minimum anywhere else. I finally, in disassembling it in disgust heard a rattle in the box as I moved it and discovered a broken toroid in the matching box.

Over a couple of weeks after several attempts to contact their service department both by phone and by e-mail I finally received a phone call from a gentleman. The bottom line was that they would give me NO information about the broken toroid, would NOT sell me a toroid, could/would NOT test traps or other parts which which he said might be bad and they'd be glad to sell me the WHOLE MATCHING BOX for well over $100. They "used to" have a test rig to test traps but they moved it to "production" now and can't test traps.

Cushcraft used to be a very fine company to deal with and if one had a problem they'd go out of their way to help and even have sent me parts free for antennas out of warranty. Now they have a DEAL FOR YOU and it's going to cost you LOTS OF MONEY and you aren't likely to want to take advantage THEIR DEAL FOR YOU when you call with a problem.

I will NEVER AGAIN buy anything made by Cushcraft. They just plain don't care anymore about customer satisfaction or whether or not their products live up to their advertising hype.

Steve,
The 'quick and dirty' answer is to find the total length
required for a full wave at the frewquency you want to
operate on. Divide that length by three, and you have the
lengths of the sides of a 'delta' loop. Divide by four to
get the lengths of the sides for a 'quad' loop. You don't
have to be exact, a little difference in the lengths of the
sides doesn't make a lot of difference one way or the other.

IF one is close to the system being considered. As you say in the next
paragraph:

> Something different happens when the reflector is at great distance from
> the radiator. The paths from the direct and reflected rays can be about
> the same length as happens at the grazing point on a microwave path.
> Depending on phasing, the two rays can combine to produce as much as a 6
> db gain or a complete cancellation. The reflection is weak, but the
> direct ray is just as weak.

The latter sentence is key to this discussion -- in the far field (ie, very
far from the mirror), the reflected ray, which does attenuate slightly going
toward the reflector (the mirror) and the direct ray are at about the same
level. What counts, with a lossless reflection, is the total path length.
The total path length differs by 2h, where h is the distance from the
radiator to the reflector. If, as you say, the reflection is lossless
(remember, this discussion involves perfect ground), then the strength of
both signals is determined only by the total path lengths involve. Whether
they are additive or destructive depends on the phase relationship between
them.

> I just tried an experiment with a flashlight and a mirror which was
> inconclusive. The light reflected from the mirror was stronger with the
> flashlight closer to the mirror, but the total pathlength was changing
> considerably. The wavelength is very short indeed.

Yes, you must be far enough away that the path length does not change. You
must also ensure that the reflecting plane is large enough that all of the

energy from the flashlight illuminates the reflector. Do note, for the record, that becuase the total path length was changing, the effects you were seeing are not the same as if you were in the far field. Could this mean that you are in the radiating near field of the system when taken as a whole? :-) What is 2D^2/lambda of a flashlight? :-)

hi phil
when it comes to lighting damage it is cost effective to replace the
antenna due to EM damage that may not show up right away as for the
fact that cushcraft doesnt have replacement parts for a new antenna its
the same way with most things i know GM and ford are that way with a new
car try and find a replacement part for a new production model car till
its been on the market awhile
good luck
oh and this comes from someone who is still waiting ion cushcraft to
send replacement parts for a 10 year old ant its been 4-5 weeks

A horizontal rhombic near ground and parallel to the ground produces an interference pattern with its image in the same manner as a horizontal dipole.

A 4-wavelengths per side rhombic may produce a main lobe at 12.5 degrees elevation angle when the rhombic is 1.18 wavelengths above ground, according to Ed Laport in "Antenna Engineering" (page 325).

The elevation angle of radiation from a horizontal rhombic comes down as its height in wavelengths above ground goes up. Laport shows less than 10 degrees elevation angle at a height of just a few wavelengths. At 180 wavelengths, I`d expect the elevation angle to be close enough to zero for practical purposes.

At 3 GHz, the frequency of my rhombic at an elevation of 180 wavelengths, the only radiation of interest is that occuring in the plane of the antenna wires. Ionospheric propagation is unlikely.

Arnold Bailey includes a horizontal rhombic in his catalog of antennas presented in "TV and Other Receiving Antennas". Bailey`s antennas are all scaled for 200 MHz. Bailey presents free-space radiation patterns and gain figures for all antennas with the understanding that height above ground can affect performance. But it makes no sense to present an antenna in a catalog in any other way.

Bailey`s 200 MHz rhombic is almost a 15 times scaled version of my 3 GHz rhombic.

I think that at 180 wavelengths above ground, my 3 GHz rhombic is little affected by ground reflection in its neighborhood. At the grazing point of a terrestrial path a reflection could affect a received signal, but this would be classed by most concerned individuals as a path problem, which any antenna would be subject to regardless of the antenna`s type.

Roy Lewallen may have wanted to make a point that an antenna several wavelengths in height would experience an interference pattern from its ground image. But 180 wavelengths above ground for propagation to a satellite overhead or to a terrestrial target on the horizon? The earth reflection will be nearly irrelevant, and Roy`s remark was gratuitous.

> to reduce common-mode currents.

When the load is unbalanced, a current (choke) balun at the load helps to assure that the current that returns from this load is forced to return via the *inside* surface of the coax. It does this by creating a potential at the braid end of the load (because of its common mode impedance) that makes this current flow possible and makes the inner surface of the braid (shield) the "preferred" conducting surface. Any current that flows on the outside of the braid is basically a common mode current that can be troublesome.

Pete -

Let me also suggest that you run your feedline straight down from the antenna as far as you can before you turn it horizontally. I had quite a bit of RFI when I ran the feed horizontal at the base of the antenna. Now I run it straight down to the ground and then go horizontal. No more RFI.

Cushcraft said they were *discontinuing sales* of the older models, NOT
that they would no longer support them. Bencher has twisted the
notification to suit their fancy, painting a deceiving picture of their
competition. Pretty lowlife if you ask me!

Hi Richard,

I will quote you from an earlier post:
>
>I`ve avoided this analogy because I`d rather zero in on an agreement

>than to enlarge the argument over what the analogy means.
and you were right to worry about analogies (which like metaphors prove to be very poor instruments in closely debated issues).

The principal mode of failure when using light metaphors and analogies is the eye. Very few people have trained eyes to distinguish the physical evidence from the psycho-induced evidence.

The eye still reigns supreme over every technology that has come down the pike to replace its functions. However, the eye also introduces pre-processing before the "idea" of what is being seen even reaches the brain. Such pre-processing makes light look brighter when in fact nothing has changed physically within the experiment. There are several many means by which the eye does this processing to achieve this characteristic.

There are also the problems not associated with judgement and are directly related to the nature of measuring light power. Most of those issues relate to matters discussed in this venue, but are poorly applied or never considered.

It is an attractive argument to treat microwaves as optical beams, but such analogies must be constrained - and those constraints would introduce far more variables than those encountered for the original topic.

Richard, your fear was warranted.

Possibly OT, but here's a couple of thoughts.

I'm taking note of the opinions mentioned here, as I was intending to invest in a vertical. Both companies being mentioned in various posts, and especially the 'note' on the Butternut (Bencher), site has made me think again about business ethics and dealing with various companies. In fact, the knock on is that I've been looking to replace a Bencher key, which I had to claim for on insurance when it was stolen. I will probably not buy a Bencher, but then I was tending towards a different make anyway, so they probably would not count me as a 'lost sale'.

However, as to whether all this will really hurt Cushcraft and/or Bencher, I doubt it. There are more Amateurs who don't read this NG than do, and most of these companies have bigger business interests away from Amateur Radio than in. The numbers of Radio Amateurs, at least in the UK, is in decline. We're starting to become even more of a minority interest than we were a few years ago, and AR, despite what 'we' may like to think, doesn't carry much weight in the business world.

So, companies like Cushcraft and Bencher could well look at the postings here and think, perhaps privately, 'so what?'

Let's not over inflate our opinion of ourselves and our influence, eh?

Economic reality is whatever it is. But a part of is that consumers
will factor those points into their buying decisions. I'd be a little
reluctant to buy an expensive antenna when I knew in advance that I
would have problems getting replacement parts for it.

Hey, some of that Junk *IS* mighty fine, as opposed to some other
brands of junk that isn't so fine.

That's not the way I see it. Informing prospective customers of your own product support policy as opposed to the competition is just good business. Maybe Cushcraft will be moved to actually support their own products better.

So far, so good.

But they completely distorted the Cushcraft statement.

Cushcraft states they have discontinued the SALE of certain old
antennas.

Cushcraft did not state that they would no longer SUPPORT existing
owners of those antennas.

The Bencher notice is outright fraud.

2420. Re: Rhombic antenna for 10m

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-15 00:00:00 UTC
From: richardharrison@webtv.net
Message-ID: <13417-3A12D81B-3@storefull-111.iap.bryant.webtv.net>
Source record: 176504

In a nutshell, reflector radiation depends on current in the reflector. The reflector may be a conductive wire, sheet, corner, screen, parabola, the earth, etc. But, no current, no radiation. A reflector with no current has no effect on a radiated signal.

The farther a reflector is from a radiator, the less induced current flows in the reflector.

At 180 wavelengths from a radiator, the field strength is attenuated about 60 db. That means a wire 180 wavelengths from a radiating wire can only have about one-millionth of the current flowing in the radiator without special tricks. (The image antenna is 360 wavelengths away, but that`s only 6 additional db of attenuation.)

Best regards, Richard Harrison, KB5WI

I like to eschew obfuscation.

Richard Clark is a most skilled writer and I admire his way with words.
He also wrote:
"However, the eye also introduces pre-processing before the idea of what is being seen even reaches the brain,"

I`ve "seen" somewhere a report that images in our eyes are inverted but set upright by the brain. I`d thought of using a light bulb power output indication to shed light on the subject of subjective measurement, but the idea dimmed because it really wasn`t a bright idea.

The Armenian judges gave this a 9.8 on the Olympic Troll-O-Meter, but they were over-ruled by the umpires in instant replay, who award it a 2.6.

The Armenian judges lodged a formal protest!

It was sufficiently trollish, of course, but way too obvious. It was poorly written, poorly executed, and was so incredibly lame as to lack the true drawing power of a really masterful troll. Maybe as high as a 3.3 for the sheer stupidity of the premise, but a 9.8? Never! The Armenian judges tear their hair out, throw their balalaikas down in dismay, and perform the traditional Armenian Dismay Chant! They demand a recount!

Source record: 176512

Ed Hare, W1RFI <w1rfi@arrl.net> asked:

:-) What is 2D^2/lambda of a flashlight? :-)

Well, lambda = 600 nm for the yellow light my flashlight
puts out and D = 1.5 inches = 3.81e+7 nm,
so D^2 = 1.45161e+15 (nm)(nm) and 2D^2 = 2.90322e+15 (nm)(nm).

2D^2/lambda = (2.90322e+15)/600 nm
= 4.8387e+12 nm
= 4.8387 kilometers
= 3 miles give or take a couple of feet

Aren't you glad you asked!

Your point is actually somewhat valid, but not for that reason. The mirrorred reflector behind the lamp, and the baffling at the front of the flashlight help to collimate the light into a beam. So in effect the lamp filament does not act as a true point source, and it's light intensity does not fall off as rapidly with distance as it would otherwise (in the far field).

My comment referred only to your experiment. Any amount of light lost in reflection would certainly not be detectable by eye.

In my "nutshell" posting, I made a dumb mistake. I said a power ratio of 60 db would produce a current ratio of 1,000,000 to 1. That is the power ratio, not the current ratio. The current or power ratio is only 1000 to 1 because the power ratio is the square of either the voltage or current ratio. One thousandth is very small (0.1%) and the current in the reflector is still insignificant, just not so insignificant.
Sorry!

Best regards, Richard Harrison, KB5WZI

Anyone considering a quad will be happey once they get it up. As far as I am concerned a quad out performs a yagi when the going gets touch and they work a lot better than a yagi at the lower hieght. I would however suggest using a gamma match on the quad. Perhaps Cecil has a better solution to keeping that static charge under control, but for me the fix was easy and made impedance matching a snap. Jim

Source record: 176518

The current or VOLTAGE ratio is only 1000 to 1 when the power ratio is 60 db. Some days I just can`t shoot straight.

Best regards, Richard Harrison, KB5WZI

Whatta shame. I had an old long-boom Cush 3-el 10/15 duobander at 80 ft. and it bored holes right thru any pileup in any dx contest back when with just an SB-200, the thing was just plain spooky, best pileup buster I ever used by far. But I had some problems with the original plastic standoff insulators they designed into supporting the driven element. Cush shipped me a whole bag of their improved versions along with a with a longwinded technical discussion and apologies. Took it down two years ago after thirtysome years up in the elements and it went back up about a year ago elsewhere and it's back cranking. Something good has gotten lost, shame.

I can't and won't define what is right for Cushcraftor anyone else. I will say that the margins on large aluminum antennas are small--when made in the US. And when extra parts are needed, this requires a separate attainment and maintaining of a physical inventory. This ends up being very expensive, relatively.

I imagine the 'high price' for distinct parts is not meant to 'rip off' or discourage anyone, but is a true reflection of the costs to keep these parts on hand. The lack of availability, until a year or more has gone by, represents a realistic sense of a minimum number of parts in inventory to keep even those expensive prices from being astronomical. In other words, you must have a NEED to even think of making an inventory.

Its not 1965 anymore, and the labor costs in China, Mexico, and Asia are so much lower that even paying (just)someone stateside to keep parts inventory costs $70-100K per year overall. Now figure out how many traps or hose clamps or tubing sections you need to sell , even at high costs, to break even. And that's just for the costs of one employee!

David, I was in a similar situation in a hotel room 10 years ago at Disney world. I used capacity coupling through the glass using about a square foot of aluminum foil on both sides of the window. I ran a 1/2 wavelength of wire on 40 (about 65 feet) from the "outside foil" to a tree. I connected the "inside foil" to the hot side of my tuner and tied ground using a short lead to the window frame. I may have added a 33 ft counterpoise lying on the ground to the frame as well. This setup worked great, worked into Europe fairly easily with 100 Watts.

Great summary Ed.

The level of reflected signal is both a function of soil conditions and
grazing or reflection angle as Ed points out.

As an example, consider the earth conditions to be dielectric constant = 15
and conductivity = 12 x 10^-3.

At 1 MHz, the amplitude of signal reflection is about 90% and the phase
angle of signal reflection is about -185 deg for all grazing angles.

At 12 MHz, the amplitude of signal reflection varies from 85% at 10 degrees
grazing angle to about 65% at 90 degrees grazing angle. The phase angle of

reflection is about -185 degrees at 10 degrees grazing angle to about -195 degrees at 90 degrees grazing angle.

There is not much difference in the values from 12 to 100 MHz (at least for these soil conditions).

The formula to calculate these values is as follows:

A = grazing angle
e = soil dielectric constant
s = soil conductivity

X = 18 * 10^3 s / (frequency in MHz)

T = sin(A) - sqrt[(e - jX) - cos^2(A)]

B = sin(A) + sqrt[(e - jX) - cos^2(A)]

Reflection Coefficient = T / B

Note that this is a complex number with magnitude and phase.

Not in general; dBm is an absolute amount of power relative to a milliwatt,
so unless you are talking about some sort of power combiner, no.

> Can I add dBm to dB?

Yes, and you get dBm, since dB is a relative gain (or loss if negative).

> http://www.mindspring.com/~w6rca

Hi Cecil,

You are correct, power is a scalar. I should have said: 130 watts = 100 watts + 30 watts is only true when the voltages and currents associated with the 100 watts and 30 watts are 90 degrees out of phase.

In a 50 ohm transmission line, 100 watts of power has an associated voltage magnitude of 70.711 V and a current magnitude of 1.414 A. 30 watts of power has an associated voltage magnitude of 38.73 V and a current magnitude of 0.775 A. 130 watts of power has an associated voltage magnitude of 80.623 V and a current magnitude of 0.62 A. This all based on the relationship that P = |V| |I| cos(theta), where theta is the phase angle difference between V and I. V and I both being in a 50 ohm system.

In the transmission line, the two forward complex voltages and currents add to become the total forward voltage and current. Recognizing that both magnitude and phase are factors in complex addition, the only condition under which a voltage with a magnitude of 70.711 V adds to a voltage with a magnitude of 38.73 V to result in a total voltage having a magnitude of 80.623 V is when the two voltages are 90 degrees out of phase.

If I understand correctly, your cable is only 50cm long, total. With so short a cable run at 13.56MHz, there's very little advantage to bothering with two cable runs. Since the length is far less than 1/4 wavelength, the key advantage would be to lower the power dissipated in the line; that's a benefit you'd not get if the line was long, but it does apply for lines which are very short (and loaded with high current). But whether you use one line or two, the load presented to the RF generator will be very nearly the same, and very nearly the value at the plasma-chamber end of the line. So in either case, it's important that the RF generator can be tuned properly into that load. If not, you can gain some advantage by using a matching network (at either end of the line, but slightly better if it's at the load end of the line) to cause the correct load at the RF generator.

Cheers,
Tom

> > Can I add dBm to dBm?

> Not in general; dBm is an absolute amount of power relative to a
milliwatt,
> so unless you are talking about some sort of power combiner, no.

As an example, 0 dBm is 1 milliwatt. 1 milliwatt + 1 milliwatt = 2
milliwatts. Restated in dBm, 0 dBm + 0 dBm = 3 dBm. :-)

> > Can I add dBm to dB?

> Yes, and you get dBm, since dB is a relative gain (or loss if negative).

As long as you realize you are multiplying, not adding. 0 dBm increased by
10 dB (10X) is 10 dBm.

73,
Ed Hare, W1RFI

1 sci.electronics.equipment

You send 3483 posts on this NG and you are not public? I'm reminded of
all the times you remind all that this is a public forum. Oh, sheeeeet,
I get it, this doesn't apply to you.
>
> Ask an attorney's counsel on this.

Who is the attorneys counsel? Is he any better than the attorney? About
the same, worse? Does he have a ph.d?
Is he a ham? Does he build antennas? Or is the counsel more than one? A

flock of sheep? A flock of seagulls?
Or is the counsel a big Texas bull? Huuummmm, maybe thats it...You know what they call cow doo-doo here in Texas don't you? A cow-chip.... MK

This should help, but if it doesn't, check rec.radio.cb for further instructions. MK

Only Wally knows for sure. I called Eddie Haskell about it, and he said
all of Chips antenna's are a bit lumpy.
I called Wally for his comments, but he told me to @#$% off.
Wally=Phil???? Hummmmm.... :(MK

2455. Re: Static noise from rain or snow

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-16 00:00:00 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8v1ove$2j7$1@plutonium.btinternet.com>
Source record: 176277

A cloud or storm of charged particles have an average
potential with respect to ground. If the antenna is allowed
to float by insulating it from ground it will aquire a
potential above ground equal to the average. The noise
level impinging on the antenna will then be minimised.

A thickly insulated antenna wire, such as the inner
conductor of a coaxial line plus the polyethylene, will be
less noisy. Probably needs a few inches of pruning to
maintain the same electrical length as an uninsulated thin
wire.

Reg

2456. Re: Testing a balun

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-16 00:00:00 UTC

Message-ID: <8v1p8s$33l$1@plutonium.btinternet.com>
Source record: 176278

Suggest you remove the balun. There's an even chance the
antenna will work better than it ever did when the balun was
fitted.

Reg, G4FGQ

Obviously, I'm a much more public person than you are. You can tell by my 65 posts compared to your 1700. Only a pd.h would think you are more public.

Will this help? Maybe just a little? I bet it will. BTW, my counsel told me to post this. He said it would be good therapy for you. MK

2459. Re: Where does reflected power go?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-16 00:00:00 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8v1qgq$m58$1@uranium.btinternet.com>
Source record: 176281

I will apologise in advance for the following comments.

Reflected power doesn't go anywhere. It is just a figment of human imagination put there by unscrupulous SWR meter salesmen and other old wives. It wasn't generated in the first place.

In a sensibly lossless transmission system, which most systems are, all the RF power outputted by the transmitter is absorbed by the intended load, ie., the antenna. There's simply no-where else for it to go.

Cecil W6RCA wrote:
"Generated Power plus Reflected Power equals Forward Power."

True if all reflected power is bounced by the generator.

I`m only sure that the reflected power subtracts from the forward power when using the Bird wattmeter to give an indication of generated power and that is the same power which is delivered to the load. This has to be because there is no place in the transmission system for long term storage of r-f energy.

Cecil`s logic holds because when you subtract reflected power from both sides of Cecil`s equation, it`s the same as mine.

Best regards, Richard Harrison, KB5WZI

Hi Jan,

You are right in most details. I reviewed that design in this group
around Feb. of 1996. I posted to this group that EVERY claim made was
supportable in the data.

If this is the spirit you find missing, then it was not for want of
trying.

Hi Jeff,

There is no inherent advantage in the claim of
>sometimes the most interesting advances come from such disruptive/different
>viewpoints.
as sometimes is not all times nor even most times (and even "sometimes" is an overstatement). It suggests that anarchy is good, but even an anarchist would blast such a statement as outside the goal of anarchy.

I can understand the basis of the statement, but even here it is a false basis in regard to the subject line being discussed. For instance I maintain a very comprehensive survey of fractal antennas at:
http://www.qsl.net/kb7qhc
that easily eclipses such material available anywhere else on the web. This site runs to some 300+ pages of data and analysis. Discussions of design merit can easily be researched from data - I provide data. The notion that this topic is new or radical is one of perception as I have investigated this line of design going on 5 years. In other words, those new to the topic find it disruptive/different perhaps, but that is simply due to a lack of exposure, not a reality of any situation.

Perhaps what you perceive as disruptive/different has been more a matter of personality and ego, not one of science and technical discussion. As always, I invite all interested parties to engage in meaningful discussion of the merits/demerits of fractals - too often it is the bloodlust and thrill of the chase that attracts attention away from this offer.

Hi Scott,

Nothing trollish about a topic that incites so many to spend so much
time responding to. Hmm, that does sound trollish doesn't it?

But, to answer your question:

Reflected power going back to the transmitter is destructive because
the transmitter will attempt to absorb it as would any load. Now the
level of destruction may simply be heat, but consider that heat can be
measured in comparison to body temperature or relative to a flame
temperature.

The principle failure mode for solid state sources strained with
mismatched loads is found in the excess current passing through the
device where its ability to support local current density is exceeded.
At this level we are talking about melting of the crystal lattice and
catastrophic destruction.

If you insert a tuner between the mismatch and the transmitter, you
are providing another mismatch (to the reflections on their way to the
transmitter) that is the reciprocal of the load mismatch. This
creates a situation wherein the power is reflected, re-reflected, and
re-re-.... you get the point. However, with each successive

reflection, some energy escapes the antenna in spite of the original mismatch (it always does) and the significance of that power sloshing back and forth diminishes with each pass back and forth (not to speak of that power lost to the transmission line supporting all this sloshing - in fact that is the major source of real loss, or in the tuner itself).

Now keep in mind the discussion above presumes a single wave to support this sloshing analogy, and if you keep in mind that every single cycle undergoes this process , independent of all cycles before it, then things will work fine.

Keep your eyes open for an announcement from Walt Maxwell, W2DU, as to when his new edition of "Reflections" becomes available, and buy a copy quick.

Might I presume to disagree Sir? Herr Maxwell in "Another look at reflections" Sub Chapter "Too low a SWR can kill you" said "judging from what we hear on the air, nearly everyone is looking for a VSWR of 1:1

Question why and the answer may be, I'm not getting out on this frequency because my SWR 2.5:1... there's too much power coming back and not enough getting to the antenna...or I feel a line having that much SWR, the reflected power flowing back in to the amplifier will burn it up..." He then goes on to Poo Poo any of these ideas. If interested I will be glad to post the reasons.

Hi Jim,

And now we drag the ear into wave phenomenon - I love it! ;-)

By the original intent of the dB, a unit of least discernible audio level change, the answer would have to be no when speaking of 1/5 of that least discernable level change. Now if you were to speak of discerning a level change between 130dB and 131dB, even then the most probable answer would be no, as the physiological limit of perception is now being taxed at the upper limit (verging on the threshold of pain). This says nothing of using the physiological scales of dBa, dBb, or dBc and the matter of the particular frequency those levels are excited at.

Here we enter into the realm of the ear applying modification to the idea of what is heard before that idea reaches the brain. The ear is not uniformly sensitive under any variation of variables (such as sound pressure, frequency, pure tones or mixed tones and so on). At certain sound pressure levels and frequency combinations, it would be arguable that you could even discern 10dB variation (which of course confounds the original intent of the meaning of dB as applied to sound).

In fact, it is probably impossible, outside of a metrology lab, to mechanistically detect an accurate differentiation of 0.2 dB spl when at the level of 130 dB (or choose any level you wish). At this degree of discrimination, too many environmental factors' variation swamp such measurements. In other words, like an antenna, this would require an anechoic chamber.

> 80.623 V is when the two voltages are 90 degrees out of phase.

This is incorrect for the following reasons:

1) The current corresponding to 130 W is 1.613 A, not 0.62 A. But we cannot look at this problem in this manner.

2) The forward power is 130 W. In terms of the forward wave this is (V+)^2 / 50, so (V+) = 80.62 V RMS

3) The reflected power is 30 W. In terms of the reflected wave this is (V-)^2 / 50, so (V-) = 38.73 V RMS.

4) The difference between the forward and reflected power waves is (V+)^2 / 50 - (V-)^2 /50 = 130 - 30 = 100 W.

These two values are what a thermoelectric directional wattmeter measures. The phase between (V+) and (V-) is *not* specified. The phase difference between (V+) and (V-) is controlled by the reflection coefficient at the load, which can be anywhere on a certain circle on the Smith chart.

For example, at a resistive load, (V+) and (V-) can be completely in-phase (or completely out-of-phase). But as we move along the line the phase between (V+) and (V-) rotates. But the forward (130), reflected (30) and net (100) power values are constant everywhere on the line.

Maxwell also wrote a series of QST articles. They are all available among the articles posted at:

http://www.arrl.org/tis/info/reflections.html

The Reflections series is found at http://www.arrl.org/tis/info/pdf/Reflect.pdf. It is just over a megabyte, but about 58 pages.

While I do not agree with the presentation of every single technical detail in the Reflections articles, they are great reading for those who would like a better understanding of the concepts of SWR. Walt and I have corresponded a bit and he told me that the presentation of some of the more controversial concepts in the series and his Reflections book will be improved for the upcoming new version.

Exactly. Same problem is found in trying to detect by eye, the
difference in intensity between the incident and reflected light from a
flashlight bouncing off a mirror. The light loss is orders of magnitude
below the intensity. Feynman has a fun, related discussion in QED.

This is an oversimplification. The result of load reflection is that the impedance presented to the amplifier may not be a) not resistive and b) not of the right magnitude.

In vacuum tube amplifiers the PI network can accommodate a range of impedances and transform them to the correct plate load resistance. No problem.

In solid state broadband amplifier the load presented to the transistors can be too low, too high and/or reactive, all of which are troublesome in one way or another. The transistors can overheat because the efficiency is too low, or the transistors can zap because of overvoltage on the drain/collector. Reactive load lines are bad news for transistors.

The question "Where does the reflected power go?" is a phoney baloney question anyway. Reflected power is the ratio (V-)^2 /50, where (V-) is the reflected voltage wave. At the amplifier output this reflected wave (V-) adds vectorially with the forward wave (V+) that is leaving the amplifier. These two waves establish a value of complex impedance at the amplifier output. This is the impedance that the amplifier delivers its *net* 100 watts (or whatever) to the load. The task then is to make the amplifer deliver this 100 watts into the resistive component of this coax input impedance.

But Walter Maxwell has expanded on that very subject. He was talking, in
context, ONLY about tube transmitters with built-in pi net tuner circuits.
That's about all there was when he wrote that article. He has said that he
was NOT talking about solid-state amplifiers with fixed 50 ohm outputs. He
has said that solid-state amplifiers can indeed eat enough reflected energy
to overheat or blow themselves up. "Reflections II" will probably correct
that misunderstanding.

> simply no-where else for it to go.

Here we go again. :-) Assume a 100 joules/second transmitter with a one second long lossless transmission line and a load which causes reflected power to equal half of the forward power. Key the transmitter.

After one second, no power has reached the load and there is 100 joules in the transmission line.

After two seconds, 50 joules has reached the load, 50 joules has been reflected, and 100 joules is in the forward wave. NOTE THAT 150 JOULES EXISTS IN THE TRANSMISSION LINE, MORE THAN THE GENERATED ENERGY.

Assuming a Z0-match which blocks reflected power from reaching the transmitter, after three seconds forward energy equals 150 joules and reflected energy equals 50 joules.

After four seconds, 75 joules has reached the load, 75 joules has been reflected, etc. etc. etc.

I think you get the idea. After steady-state has been reached there is 200 joules of forward energy and 100 joules of reflected energy. The transmitter has generated 300 more joules than has been absorbed by the load. There exists 200 watts of forward power and 100 watts of reflected power. It really and truly exists because it hasn't made it to the load yet.

There **IS** somewhere else for it to go, Reg. It is *stored* in the transmission line until the transmitter is turned off. Without the reflected energy stored in the transmission line, all the generated power would not make it to the load.

Before we talk about lossy lines, we need to talk about lossless lines
in order to answer his question, where does the reflected power go. See
my followup posting to Reg. Even Reg forgets that the transmission line
must fill up with energy before the load can accept all the generated
power.

They eat themselves up, do to the mismatch of impedance. Lets put a tuner in line so the impedance is matched. I think you would agree that the SWR on the line has not changed one iota, (disregarding lengths of wire in the tuner) now we are back to Maxwell's original premise.

Hi Jim,

Exactly? There is no correlation between the function of the eye and
the function of the ear - especially with a brain in the middle. ;-)

Home Depot sells aluminum electric fence wire in 17ga. I've used it for a 160m horiz loop and it lasted 5 years in high winds due to it's light weight. At the feed point, smear it with dope and use wire nuts for the connection.

Yuri Blanarovich, K3BU wrote:
"Don`t work! When I designed Razor Beams, I used insulated wire for quad elements and all yagi elements were grounded to the beam and tower."

Glad you got some relief from precipitation static with an umbrella effect. I visited with Ed Laport when he was RCA International`s chief engineer. I was favorably impressed. Ed put in receiving stations as well as transmitting stations worldwide. He llikely had much experience with precipitation static. I had no serious precipitation static in my experience with receiving stations. Guess I was working in better climates. I`d bet Ed was speaking from experience in his book.

I can imagine a charged particle separating from a cloud producing a tiny capacitor with a growing separation between its plates. Lessee, Q = CE. or E = Q / C. As our charged particle moves away from its other plate, C shrinks while Q is fixed and E soars. By the time it lands on something it can produce quite a pop when it discharges unless there is a really hefty insulation to prevent immediate discharge.

Ed didn`t say how much insulation was enough in "Radio Antenna Engineering". Reg Edwards suggested coax without the shield as possibly suitable.

Maybe Yuri`s quad elements might have been more immune to precipitation static with heavier insulation. I haven`t a clue as to how much is enough. Maybe there are other reasons the static kept coming on Yuri`s insulated antenna elements. Reg Edwards had another suggestion, to let the antenna float above ground acquiring a high charge to repel rather than attract particles. Would that bring on the blue balls of fire? There probably are many stories of success and failure in the attempt to eliminate precipation static.

Best regards, Richard Harrison, KB5WZI

"If it works, don't fix it" or "prevention is better than cure" -
choose your proverb.

>When an authorised station, complying with regulations, is
>surrounded by nearby TV receivers a choke is just as likely
>to make TVI worse as to improve it. Particularly on the 160m
>to 30m bands.
>
Why "just as likely to make TVI worse"?

>Since most of the trouble is due to TV installations being
>too sensitive to frequencies for which they are not intended
>(or authorised) to receive it is often more effective to
>cure the problem at the receiving end.

The point you're not addressing is the social one, about causing
problems to other people. If you can take precautions to avoid causing
problems, that's far better than letting the problems happen and then
fixing them.

That is an interesting question.
My suggestion is to let your neighbors, especially any new ones, know you are a ham--but that's that. If they have a problem then they will tell you. Otherwise, if you make yourself an RFI 'fixer', without any existing problem, you become the receiving end of needless complaints. This will undoubtedly get exponentially worse as the wireless internet kicks in.

Be sure to ask them what, how, and WHEN the 'problem' occurs. WHEN is critical; about half the time I am 'blamed' for RFI when I am not even home, and the rig is off and cold. I'm sure my experience is not unique in this.

2484. Testing a balun

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-16 00:00:00 UTC
From: Colin Marks <cbm@zip.com.au>
Message-ID: <3a13a119.13273@nancy.pacific.net.au>
Source record: 176320

I use a half-wave dipole antenna tuned for 20 m. band and fed with about 50 feet of RG8 co-ax plus about 25 feet RG58 for the last run to the centre of the antenna. There is a RAK balun at the antenna centre. I have had excellent results with swr never more than 1.3 to 1 until recently the swr suddenly shot up to about 5 to 1 - a level to high for me to operate. This happened in the middle of a QSO. I operate ssb and the power would be about 400 watts pep.(legal limit here) but sometimes possibly tested briefly at 700.
The antenna is very difficult to access and I do not wish to take it down for testing unless unavoidable.
The fault must be either in the balun (which is fairly new) or in a co-ax connector.
My question : can I check the balun from the shack in some simple way to avoid taking down the antenna?
From the shack the two sides of the co-ax feedline test open-circuit. This seems to indicate a fault because I think both sides of the balun should be short circuit to DC (open circuit to RF). This could mean a break in either a connector or internally in the balun.
Any comments would be appreciated - preferably by email.
Thanks.

> 80m Novice Band in '53 with an 80m ARC-5 and tally-ho!

You were richer than I was. The S20R was all I could afford. After I got my ticket I saved up some more and I got a BC458A surplus transmitter, 5.3 MHz - 7 MHz if I remember correctly, and turned the padder capacitors all the way out so that it covered the bottom 100 KHz or so of 40. Cost $5, somewhat cheaper than the BC459A that covered 40 already, and I figured I could make it work and I was right. Soon thereafter I bought the black Navy version of the BC457A, 4 MHz - 5.3 MHz, for another $5 and turned its padder capacitors all the way in, rather than buying the more expensive one that already covered 80. After retuning, it barely made it down to 3.5 MHz, so I didn't have to worry about going past the band edge. Nice bandspread, done that way! 80 took up almost the whole dial. Worked VKs and ZLs from Ohio with the thing in the dead of night on 80 metres when I should have been studying mathematics. Someone stole the S20R from my college dorm room a year or so later in 1952, and I couldn't afford to replace it, so I sold the two Command set transmitters for I think $10 apiece, and threw in the power supply I had crafted out of pieces of old radios as part of the deal. I must have had thousands of QSOs with that lashup before it and I parted ways. I think my total cost for all my gear including a cheap bug key was about 60 dollars. By the time I got my Extra in 1955 I had no equipment and less money. I could copy 55 wpm in my head, and send 35 wpm, whenever I got to use someone else's rig.

Birken,
You can use almost anything that's an insulator. PVC tubibg, other
kinds of plastic, etc. You can also 'tie-off' to different trees,
poles,
what ever. The more seperation between 'elements' the better, but
seperation isn't too critical...

It sounds like the problem is with a disconnected braid, probably at the feedpoint. Reflectometry can confirm the place of the break. I think the MFJ 259B does this, but have not used it in this mode.

Some baluns, such as bead baluns, will given an open circuit when you check continuity.

I fear you have fried something in your balun. What power is it rated at?

Source record: 176324

Near field noise pickup folks:

In either case, well designed coaxial transmission system or well designed parallel line feeder transmission line, the near field noise pick up will be minimal, since neither will respond to common mode noise. At HF ladder line is no better nor any worse than coaxial cable for near field noise pick up.

In fact often a typical ladder line installation will be superior to a coaxial transmission line for near field noise pickup simply because the installation and maintennance is done more carefully. Many are "lulled" into thinking that coaxial cable "automatically" will reject common mode noise, and fail to pay attention to cable routing and dressing and to good balance and common mode rejection techniques. With ladder line, you are almost forced to "do the right thing", while with coax it is easy to get sloppy.

I have often seen amateur installations where the ham switched from a poorly installed coaxial cable transmission line to a ladder line installation [with the "proper" baluns in line] where the local near field noise pickup was 10 - 20 dB less than with the prior coaxial cable.

So don't be afraid of ladder line wrt local noise pickup, the rumors just simply "ain't true"!

I've been able to quickly get dead flat 1:1 matches 160-10m with my 969 every time with a number of completely random endfed wires and some of those have had very "hot" ends which is a scenario many tuners can't handle. I've never tried it with any type of balanced line or coax fed dipoles. My only complaint with the 969 is that the turns counter is unreliable, "slips it's cog" and loses it's place which is annoying. It's a mechanical problem, one of these days I'll dig into it and fix it or ship it back to MFJ for repairs or butcher it and install a good turns counter.

Actually, in the last 10 days or so, Chris Trask tried. And I ignored him. In fact, he likes it so much he tried a second time. That stuck. Why? Because he'll just keep on saying incorrect misinformation, at my expense, until I respond.

So I responded. Now we know what motivates Mr. Trask.

Ask him about his beliefs regarding the CFA (cross field antenna).

This is ham radio's own home-grown pseudoscience.(Almost all the articles written about the CFA have appeared in ham publications).

Just what we need, at a time when hams have to make a case for our continued privileges of spectrum--so much for technical conttribution.

See if extant scientific fact is now acceptable to Chris Trask. See how he conducts himself when someone with authority, reasonably tries to present a scientific view.

Maybe this time he will be less willing to get others who do so banned, especially if there are many of those who do not have a 'belief' about the CFA--but speak from an understanding of electromagnetics.

Scientific and social advances may indeed come from the expression of viewpoints that create a disruptive response in some people. But those advances invariably do not come from the disruption, but from the sometimes few who choose to respond to the original expression in a scientific and social manner.

Actually, in the last 10 days or so, Chris Trask tried. And I ignored him.
In
fact, he likes it so much he tried a second time. That stuck. Why? Because
he'll just keep on saying incorrect misinformation, at my expense, until I
respond.

So I responded. Now we know what
motivates Mr. Trask.

Ask him about his beliefs regarding the CFA (cross field antenna).

This is ham radio's own home-grown pseudoscience.(Almost all the articles
written about the CFA have appeared in ham publications).

Just what we need, at a time when hams have to make a case for our continued
privileges of spectrum--so much for technical conttribution.

See if extant scientific fact is now acceptable to Chris Trask. See how he
conducts himself when someone with authority, reasonably tries to present a
scientific view.

Maybe this time he will be less willing to get others who do so banned,
especially if there are many of those who do not have a 'belief' about the
CFA--but speak from an understanding of electromagnetics.

Dear Dr. Cohen,

I must defer to your opinion on this subject since you are the
resident expert in pseudoscience.

You really shouldn't object to being treated as a public figure since
it was you actions that have made you a public figure.

I hope this helps.

Jerry

Source record: 176345

Ian, it doesn't make sense to fit a choke if the very next thing to do is to take it out again to see if it is needed. ;o)

When an authorised station, complying with regulations, is surrounded by nearby TV receivers a choke is just as likely to make TVI worse as to improve it. Particularly on the 160m to 30m bands.

Since most of the trouble is due to TV installations being too sensitive to frequencies for which they are not intended (or authorised) to receive it is often more effective to cure the problem at the receiving end.

It is time TV receiver manufacturers and installers complied with the rules regarding susceptibility to interference from non-TV frequencies. Also the rules regarding pollution of the air-waves.

All 3 of my few personal experiences arose because of defective receiving installations.

(1) The TV receiver had recently been returned from the local TV repair workshop. The so-called repair engineer had forgotten to replace a screening box after changing a valve. The GPO RFI Dept closed down my station for 5 weeks until the problem was sorted out. I had obtained the RFI complaint form and had assisted the neighbour to fill it in. We remained on the best of terms.

(2) A VHF stereo receiver had very long cables to its pair of speakers. I could be heard on SSB in the speakers even when the receiver was switched off. The speaker cables were acting as a dipole. The emitter-base junctions in the power-output transistors were demodulating my transmissions. The cure - a pair of RF chokes in the speaker cables.

(3) Neighbour with zero technical knowledge had 3 TV receivers on a coaxial 'ring main' fed from one antenna on the chimney. Problem mainly on 7 MHz. The cure - one coaxial choke adjacent to one TV receiver to break up the ring resonance.

Perhaps the most valuable purpose of a feedline choke is with a multi-element beam antenna. A choke MAY prevent feeder radiation interfering with the desired radiation pattern. But much depends on how the RF gets onto the feeder

in the first place. A choke may just distort the pattern
in another beam direction merely because it shifts the
common-mode standing waves on the feeder up or down relative
to the antenna itself.

We've been here before. If it works - don't fix it.

2510. Where does reflected power go?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-16 00:00:00 UTC
From: "Scott M. McClements" <yetbbwa@grove.iup.edu>
Message-ID: <3A1433B7.803B84DD@grove.iup.edu>
Source record: 176346

I have a few questions about reflected and antenna tuners. First off, where does reflected power (SWR) actually go? Is it eventually radiated from the antenna, dissipated by PA transistors or is it more complex than that?

Next, if you use an antenna tuner, this will improve how well your antenna "couples" with the feedline, correct? It can actually improve how much power is put into the feedline? However, the mismatch still occurs at the antenna feedpoint and the percentage of reflected power is still constant? With the antenna tuner in place, does this effect how or where a reflected wave acts?

I know this sounds troll'ish..but I am serious about what I am asking.

Thanks,

Scott McClements.

2511. Re: Testing a balun

Newsgroup: rec.radio.amateur.antenna

Colin,
Getready to take the antenna down, sounds like you
have an open balun, or connector, maybe.
'Doc
PS - Try it without the balun.

2512. Using 2 paralell 50ohm coax's instead of 1 for 25

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-16 00:00:00 UTC
From: Ash <ash@gravitywell.org>
Message-ID: <3A140DA4.E912A1EF@gravitywell.org>
Source record: 176348
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

This isn't really an amateur radio question but almost :) ,
at work we have a standard industrial rf generator for 13.56MHz,
operates at powers from 5W to ~800W.
This macine produces a gas plasma inside a vacuum chamber.
This plasma is closer to 25ohms and the manual recommends using 25ohm
cabling instead of 50.
At this point we have a little mismach resulting in some reflected
power.
Someone suggested using two paralell 50ohm cables but I am somewhat
sceptical.
Still, it's pretty low frequency (not exactly microwave :) and the cable
isn't taller than
say 50cm so cutting two identical lengths should pose no problem.
But will it help? Connectors must still be 50ohms since that's all we
can find,
at least for RG-217 cable with hv-N connectors, and the plasma chamber
is still matched
for 50...
The question is would we gain anything from doing this if it's even
possible?
Would appreciate a reply,

Regards //Anders

hi adam
a G5RV dipole is a very picky antenna it has to be installed just so or it will
not tune properly and since your telephone line is so close to your antenna
thats why you have RFI the phone line is not a sheiled line and a auto tuner
will handle a 2.1 swr but not much higher
what i would suggest is since it sounds like you live on a very small lot is to
buy an HF vertical like the GAP or the butternut or the cushcraft R7 or R8 these
are all multiband HF verts and are ground mounted so you wouldnt need much for
ground radials
good luck

Maybe in poor taste, but when taken in light of the complaints here I doubt
that they are misleading.

I had planned on getting one of the "big" 40 through 10 multiband antennas.
The thing starts with three elements on 40 and covers all WARC bands, but I
think I'll try to find a different source for a "proven" antenna.

For VHF and UHF I've been using the C3i antennas and they have excellent
customer service.

Yes it's possible and practical to use a parallel pair of cables. If the frequency is low and the cable length is short, there isn't much to be gained. If the length is less than about 1/10 wavelength it's short.

On the other hand, if the length is over 1/4 wavelength, consider increasing it to 1/2 wavelength and you will have a good match with any impedance cable.

Use of 50 Ohm connectors for 50 Ohm cable is proper. If you are using two cables, use two sets of connectors. But again, if the frequency is low, the connectors aren't important.

2520. Re: Where does reflected power go?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-16 00:00:00 UTC
From: Adam <digipoint@hotmail.com>
Message-ID: <8v183g$150n$1@news.kabelfoon.nl>
Source record: 176356

Scott,

You are having some interesting questions there. Maybe I can help you to answer them. First of all the reflected power will be changed into heat by the PA transistor or tube. As long as the PA can dissipate the heat there is not too much danger (within limits).

The antenna tuner can be seen as a sort of impedance-transformer that transforms the 50 Ohm of your rig into the impedance of your whole antenna (including the feedline etc.). When the rig can see 50 Ohms it can give it's full power and no power is coming back into the rig. So the PA of your transceiver will be very happy. However there could be still a 'standing wave' at your antenna which would mean that the antenna is not dipped for the required frequency. It will mean that it doesn't have the efficiency of a antenna that is dipped for the right frequency.

So you see, the antenna tuner doesn't do anything about standing waves. It just corrects the impedance mismatch between the transceiver and the antenna system. If your antenna is dipped for the right frequency, for instance 1/2 wave end fed, then the antenna is okay but has not the 50 Ohm impedance that your feedline and rig like to see. Normally one would use a balun transformer (1:4 for instance) at the feedingpoint of the antenna to transform the antenna impedance to 50 Ohms unballenced. If you don't have the right connection between feedline and antenna the feedline will become part of the antenna and starts to radiate energy. Your neighbors might not like it very much because TVI can be the result.

Where does the reflected power go? Well, I guess that the answer is blowing in the wind. If you could feel the heat of the coil in the tuner when you tune a bad SWR you will know where the power goes (don't do it if you don't want blisters on your hands or worse).

Well, there are many nice books about antenna's and feedlines. There is much more to it than I can write here. And I'm sure that there are many radio amateurs who have lots of experience with homemade antenna's and can tell you more.

Colin,

It sounds like you have a loose contact somewhere. I would recommend that you first check your feedline and connectors. Also check the connectors for corrosion ande bad contacts. As your problem happened all of a sudden it can also point at a defect inside the balun. Maybe it got too hot and a wire got loose inside the balun.
There is an other possibility which seems unlikely here but it could be that there is water in your feedline. Did you tape the connectors that are outside the house?

Scott McClements wrote:
"where does reflected SWR actually go?"

Ideally, to a ratio of one.

SWR is an interference pattern created by forward and reflected traveling waves on a transmission line. Voltage and current create their own similar patterns, but it is easy to measure and plot the VSWR using a slotted (trough) line.

In a lossless system, all reflected power is finally radiated. None is absorbed back in the transmitter or spent in transmission line or matching networks. SWR indicates temporary storage of circulating energy in the transmission line. Some energy is wasted in all the actual equipment used.

Typically, losses are small and often less than many people think when they see the SWR number.

Next, an antenna tuner should let you transform whatever load impedance appears to your desired load impedance. This is often the impedance of the coax you are using. The impedance desired is frequently 50 ohms which is the impedance many transmitters are specified for as a load at which the transmitter will perform as expected. Other impedances are sometimes specified.

The tuner eliminates a point of reflection between itself and the coax by providing a match. The coax then has an SWR of one.

Best regards, Richard Harrison, KB5WZI

> With the antenna tuner in place, does this effect how or
> where a reflected wave acts?

An antenna tuner cannot change the SWR at the antenna but a tuner
can achieve a Z0-match so no reflected power reaches the transmitter.
From a magnitude standpoint: Generated Power plus Reflected Power
equals Forward Power. Because of transmission line losses, Reflected
Power will be maximum and Forward Power will be minimum at the
antenna. Thus the SWR is highest at the antenna and lowest at the
antenna tuner (assuming the tuner is located at the transmitter).

Having only designed a couple of photometers, I probably woudn't know anything about that. But the point is not that the eye is detecting an absolute light level, but a relative one, in which the two light levels are very nearly identical. Can your ear discern the difference between 130 dB spl and 130.2 dB spl for example?

Sorry to all for belaboring a small point.

Sounds right to me, if one of these points is returned someway to ground.

Ed Laport in "Radio Antenna Engineering' says the way to eliminate the noise of small charged particles contacting the antenna and lead-in wires to discharge is to use wires with sufficient insulation to inhibit the sudden discharge.

Not necessarily. If the source generator does not habe the same impedance as the transmision line, part of the reflected power will be re-reflected, adding to the power from the generator. This is always true in 60 cycle power systems, where the source impedance is a small fraction of the load impedance. It is also true in most RF amplifiers, those where the efficiency is greater than 50%.

A typical situation for an amplifier is:
power to line= power from amplifier + re-reflected power: say 130 watts=100 watts + 30 watts
Power to load = power to line - reflected power: 130 watts-30 watts=100 watts for this case: the transmitter output is delivered to the oad(neglecting line loss, which causes the SWR at the ampllifier to be less than that at the load)
w4mb.

Hi Bob:

> Power to load = power to line - reflected power: 130 watts-30 watts=100

This statement is correct in all TL systems, I do however, respectfully
disagree with the following statement:

> power to line= power from amplifier + re-reflected power: say 130
watts=100
> watts + 30 watts

power to line= power from amplifier + re-reflected power is true but these
powers add as vectors since the V and I associated with the powers are
complex quantities. 130 watts = 100 watts + 30 watts is only true when the
100 watts and 30 watts are 90 degrees out of phase.

First I would listen, are signals down from where they normally are? If not, I would be looking for a broken shield connection at either end of the coax. The ohm meter has confirmed the circuit is open, that is if it is a 1:1 balun and not a choke balun. Even though it may be hard to access, the connection between the RG8 and 58 could be a problem.

I would first check the connector on the radio end. Next I would look at the connection at the junction, and then bite the bullet and check the connector at the balun. In most cases, the power you run on 20 meters will not burn out a balun. What model of balun are you using?

Look: I do NOT appreciate being publicly 'filed' as a post. I am not a public figure. I am not a target for every potential person with a keyboard to take pot shots at.

Believe me--I would like nothing BETTER than to NEVER be talked about here! So let's stop this travesty that I want 'attention'. I most certainly do not.

Please keep any abusive and judgemental comments to yourselves. Or imagine what your life would be like to wake up to abuse and malcontent EVERY day, on public forums and a slew of e-mails.

Just --please-- be quiet. Keep negative personal opinions about individuals off public forums. There was a start on this-- and now we see a growing public chatter only opening it up wider.

Thank you.

Shalom.

Nathan Cohen, Ph.D.

Happily there are other sources:
http://www-tsc.upc.es/eef/research_lines/antennas/fractals/history.html
It's a pity that that the technical discussion of Steve, Roy and Nathan
ended is this mess.
One of Nathan's creations, the FRACVERT HALFWAVE, is a clever
vertical described by Nathan about 3 years ago, with good directional
properties which can be made with a single pole support, good usable
on the lower HF bands, (I don't agree with Nathan's claim on some points)
which certainly deserves a place in ham antenna publications.
Reading rec.radio.amateur.antenna posting of 3 years ago makes me sad.
Hopefully this newsgroup will return to the same spirit it had.

Ok...point taken, unnaceptable post.... and I'd like to extend appologies to all on this group. As I said pointed out in my second post in the cold light of day it didn't look good...in fact downright out of order. Now I have been fully chastised I'll crawl back in my hole. As I said I was a little dismayed at what I read over several previous days and (like always) I picked the wrong time to add comments of my own. So take it whichever way you like I wasn't out to pick a fight.

Consider it as being nothing more that reaping the benefits of
what you yourself have sewn on this newsgroup and elsewhere for the last
couple of years.

If you want to cease being the centre of controversy, then don't
create them and don't encourage them. The only times that you have ever
come under fire is when you yourself have burst forth here and elsewhere
threatening lawsuits, claiming that you have received death threats, and
a wide range of other abuses that you and you alone have perpetrated
time and again IN PUBLIC.

Which is why you, and you alone, have been removed from various
mail lists and discussion groups. Go find a mirror and discover the
real source of your troubles.

You can glean a wealth of that sort of information from the archives of this NG in Dejanews by using various search words...attic antenna, stealth, antenna restricted, etc.

Again, more prevarications posed at my expense.

Here is a fact in point.

Mr. Trask, a Penn State educated graduate MS holder, got onto the Antennex board, and made concerted efforts to prevent anyone from making valid scientific comments regarding the so-called CFA antenna.

In other words, Mr. Trask was using this soapbox to advocate PSEUDOSCIENCE. He is a big supporter of the CFA.

The CFA is a very electrically small antenna which claims high efficiency and NEW PHYSICS to explain said claim. This is bogus, despite the near-worship, which some, such as Mr. Trask have, for this faulty premise.

The CFA has been debunked by many objective and sober colleagues, including Dr. Jack Belrose, VE2CV, whose writings are well known to many here.

Trask latched onto my cordial and objective comments and tried to turn them around so as to make me appear, and to make them appear, something they, and I, are not.

The fact is that I called a pseudoscience a pseudoscience. I will continue to do so.

The pity here is Trask is someone with some degree of scientific training, who thus is expected to know better. Certainly he should know better than to hound someone with a knowledgable basis, as is the case here. Certainly he should know bettr than to hound the folks who run such a bulletin board until they decide to effectively support the pseudosceince by quenching the scientific voice pointing this out.

In other words, ham radio, through manipulation of certain public channels, now has its own pseudoscience, thanks to the efforts of Chris Trask and a few others.

As it stands, Trask is a supporter of a known pseudoscience, who takes more than objection to a scientist calling a pseudoscience a pseudoscience.

Objection is more than welcome: I have dealt with this extensively with UFO folks--who, by the way, are ALWAYS friendly. ESPECIALLY when you disagree with them from a factual basis.

Misinformation; censure; and prevarication, which Trask promulgates here, are NOT acceptable.

Nathan Cohen, Ph.D.

What 'claim' do you find invalid? Feel free to drop me e-mail on this:

chipn1ir@aol.com

>which certainly deserves a place in ham antenna publications.

Excuse me; do you mean ADDITIONAL ones?:-) It has already appeared in two: 73 Amateur radio, and DX Magazine. That's enough.

>Reading rec.radio.amateur.antenna posting of 3 years ago makes me sad.
>Hopefully this newsgroup will return to the same spirit it had.

Pending litigation is likely to assist in that direction. I will do my best with the two which are proceeding.

Jan, please do not use me as a 'thread'. I think you'll understand how irritating this can be, as well as embarrassing.

From now on I will create a thread with each person's name, who declines earlier request NOT to use Nathan Cohen' as a thread name.

Thank you.

Yupper, I remember it well! More like "thump thump" when the guy was loud. I was never able to actually able to copy cw with the thing though, but I lusted for being able to do that. A buddy of mine now n3rs not only was able to copy it, but actually went into the 80m Novice Band without a BFO and worked scads of qsos in that mode. I decided to go for the Boy Scout Radio Merit badge which required building a one-tube regen with which I could copy cw and things moved really fast from there.

Ancient stunt. My buddy who could run cw without a BFO eventually scrounged a Heath grid dip meter and ran it's oscillator against the incoming sigs. One hand on the J-38 and the other all over the two tuning dials.

My 75M delta loop was designed using the handbook formula for a full-wave quad loop. The apex is about 70 ft (hanging off the tower from a 10 ft mast section acting as a parallel boom) and the bottom wire is about 10 ft off the ground. Am using a standard 1/4 wave length of RG-11 72 Ohm cable for the corner fed impedance match to 50 Ohms.

How does it work?

It's OK for close to medium commo and appears to have nearly an omni directional pattern.

I can only half agree with this. The post in question was certainly
a mean-spirited mistake. I can whole-heartedly join you in putting
it down as an example of the worst sort of online behavior. Where
we do not agree is the point about calling its author a lowlife.
All that does is add to the nastiness.

I don't blame anyone for feeling inspired to speak up when they
disagree with what someone has posted here, or have a problem with
how someone is conducting themselves.

The personal attacks, however, are...well...an example of the kind
of thing I don't blame anyone for objecting to, and not a proper way
to make a point.

I agree. If (ahem) *everyone* would refrain from posting their negative personal opinions about individuals here, the improvement would be enormous.

A lot of times, it helps to remember to treat others as you'd prefer to be treated yourself. I know I've offered that advice (mostly in private email) a number of times.

I'm sure everyone who opens the newsgroup only to find themselves the object of personal attack (as opposed to respectful disagreement, which is altogether different) would prefer that others make the effort to improve their efforts to disagree, and when necessary, even object to the way someone behaves here, without attacks, lamely founded accusations, negative personal opinions, and all that other ...uhm... questionable... behavior.

Well said, Chip!

I am not posting this to discredit your experiences, I am mearly going to give you my recent very good experiences with Cushcraft. I bought a AR27013S 6m, 2m, 70cm Beam in September. I had a problem with high SWR. I called Cushcraft left a mesaage. they called back within 10 Minutes and after several calls back and forth found the problem to be my ignorance.

The problem has since reoccured and I thought ok, I will buy a new reddi match assymbly. I placed my order and explained the problem on their website form. Low and behold, they call me back and stated that they were sending me the new reddi match assymbly at no charge. Maybe it is just me, but I did not expect that from them.

I also bought an MA5B. I opened the package on a Monday, to find that one of the rubber boots that cover the end of the traps had a small pucture in it. I called them again Monday afternoon. I told them I wnated to put the antenna up the next weekend. Fed Ex arrived on Friday with the replacement

Maybe my expectations are low, but from my experiences I am pleased with my recent experiences with Cushcraft!

: 2. I have no idea why Doc says that baluns do not stop RFI/TVI.
: Thousands of people have proved that they do.

Doc was probably thinking about RFI/TVI that originates from antenna
radiation. A balun will not affect that.

But, as you state, RFI/TVI due to radiation from the coax can be
reduced or eliminated by the proper use of baluns or chokes.

Andrew- a part of the answer is easy- since the ladder line direct to the xcver gives pretty good reception, the problem has to be in the tuner or the coax link. On the tuner, check the switch positions- I have seen them off sync- then check the balun. Do this as you did the ladder line- hook it to a coax input station on the tuner and see. If it is good there, that also indicates that the coax link is OK-
As an aside- I bought a used MFJ tuner, and found a problem similar to yours- After much checking- I found the posts on the ladder line input were coated with something. I could get a reading with TIGHT clips that were twisted enough to cut through the lacquer or hairspray that was on there. After I wire brushed the posts and nuts, everything was fine. (I wondered if the low price I paid was because the guy couldn't get it to work)

In other words, try everything in and out of the setup.

Good luck - Bill W4BSG

Thanks for all the comments guys.
FWIW, when I contacted Rohn, they told me I needed a 4x4x4' base.
A bit bigger than I had expected, but I'm over half there now.

I would still like to hear about pitfalls to avoid, etc.
This is my first go around with a tower, so I'm
trying to "learn from others mistakes."

I'll be making my base slightly deeper than 4' so I can line the
bottom with gravel - for drainage. I've heard some people also
put a first layer of sand down. However, an army engineer
that I talked with reccommended skipping the sand. We have
a mostly clay & rock soil here and he thought it would just
hold the moisture.

The base of the tower will be wider at the bottom than the top.
The sides are "scalloped." The corners are square.

I will have at least 4" of concrete above ground so that water
won't run over and into the base where the bottom section
protrudes.

I will be making a "basket" of 1/2" re-bar around and through
the bottom section. (Neither the re-bar nor the section will
be in contact with soil. Avoid rust.)

My ground rod will go into the earth beneath the base,
attaching to re-bar/tower section and protrude through top
of concrete.

The Army engineer also suggested I coat the bottom section with
oil to help with rust prevention.

I guess one of the fun parts will be trying to get the bottom section
aligned correctly. (I'll be using a standard 10' section.)
I'm thinking 4' level and/or maybe a plum-bob.

I'll be using 4500psi concrete as it's only $4 more a yard then
3000psi. (Oh yeah, make sure ground is damp before pouring so
that the ground doesn't suck the moisture out of the concrete.)

I'll let the concrete cure for 30+ days before going to the tower
erection phase.

Am I missing anything?

About the "Aluminum came from there in the first place"- true, but NOT
in the form of metal. The aluminum extraction process takes LOTS of
power to reverse the way nature intended the stuff to go, to get metal
from ore. the metal-to-ore process (oxidation) is the easy way that
nature will take.

George, I believe the longevity of aluminum in soil is a function of
the acid level in the soil, or more accurately its alkalinity, which is
what actually 'eats' the aluminum. Where I live it will last underground
forever.

VE9SRB wrote:

> The only impedance
> that the amplifier ever "sees" is the transmission line characteristic
> impedance ZO. It never really ever "sees" any other physical impedance.

This is not true. The transmission line equations definitely predict very accurately the input admittance (conductance and susceptance) of a transmission line that is connected to some arbitrary load impedance. The real power that is delivered to that admittance from the amplifier is the voltage squared times the input conductance. [This power, minus line loss, is the load power. Extremely easy to calculate.] This complex admittance is what the amplifier sees. The value of this admittance is determined by the composite voltage (forward and reflected) and by the composite current (forward and reflected).

The output admittance of the amplifier, which is essentially a lossless dynamic resistance, should be considered to be part of the amplifier, and not of the coax input admittance. Also, re-reflections do not have any influence on the input admittance of the coax.

The output connector of the amplifier is a "reference plane", just like in a network analyzer. To the left of this plane is the generator, a current source in parallel with a dynamic resistance (this is slightly idealized, of course). To the right of the plane is a coax input admittance that is due entirely to the vector sum of forward and reflected voltages and forward and reflected currents. This plane is a point of precise equilibrium between the voltage and current arriving from the left and the voltage and current leaving to the right. At this point of equilibrium, all so-called re-reflections are reconciled, and as a result they do not play any further role. For example, re-reflections do not influence coax input admittance.

Re-reflections influence the voltage and current levels into the coax (but not the admittance), but only if there is a reflection. No reflection, no re-reflection. From a circuit standpoint, the bottom line on re-reflection is that the output admittance of the amplifier is in parallel with the actual load admittance. If the load is not Z0 then the dynamic output admittance produces an effect that we have been describing by the so-called "re-reflection". This is an example of how a very simple circuit idea gets screwed up with a lot of wave mechanical claptrap.

I guess I must be pretty dense, but this wave-chasing drives me nuts. The "circuit" approach in the amplifier and the transmission line equations on the coax (derived directly from Maxwell's equations) are so elegant and straightforward and correct, that I really do get bored with the confusions of chasing waves back and forth. Once we have mastered the basic ideas of how wave mechanics works, its time to move on.

Back in the old days when complex computations by hand were difficult, we needed these mental intuition-aids. Nowadays, with personal computers, the Smith chart and the highly perfected mathematical equations and simulations, I keep wondering why we don't move into the new millenium.

Cecil, there's one result which should be highlighted.

At 18.14 MHz, your EZNEC-derived G5RV dipole feedpoint
impedance was -

Z = 44.3 - j290 ohms.

At 18.10 MHz, a difference in frequency of 0.22 percent, my
VARNEY.exe-derived G5RV dipole feedpoint impedance was -

Z = 44.2 - j296 ohms.

When one considers the unbelievably different computational
methods of producing these two results, it is most
reassuring, indeed gratifying, they should be so close to
each other.

Cec, you won't have to re-write your website !

Can you persuade your 450-ohm ladder-line supplier to
re-advertise the stuff as 385-ohms? Which is what it really
is. Otherwise, sooner or later, somebody is sure to blame my
programs for the difference between predicted and computed
results. I am liable to be sued for 'money back'.

Hummmm, that seems weird to have the bottom antennas quiet if the cause
is wideband noise caused by charged particles. Seems this would effect
the bottom antennas also if this was the case. I've had this noise many
times, and have tried things like quickly grounding the antenna and then
switching back to it real fast to see if the noise changed. It never
seemed to make any difference. So it didn't seem to be from any built up
charge on the antenna wires that could be discharged to lower the noise.
I would just have to wait it out. I would notice many times the noise
did seem to build up though. It would "tick" faster and faster as if

something in the area was indeed building a charge up and arcing to something. I'm wondering...maybe you were streaming as in lightning. This would explain why the lower antennas were quiet. The top antenna acts as the lightning rod, and streams, where the lower one doesn't.??? If this is the case, it would seem to me that adding a lightning rod above the top beam should make it quieter also, unless you are receiving rf from arcing. I'm not sure if insulated wire helps any at all. Maybe a bit, but I think I still get the noise with the insulated wire. All my present wire antennas are from #12 insulated copper wire. I'm guessing the insulation good for 600 volts +-??? .So anyway, maybe trying a lightning rod above the top beam would help it. Worth a try maybe..Also I would think if something in the area is streaming it would generate noise that could be heard in the receiver. After all, it's an arc of sorts. Should be noise from dc-light nearly I would think. MK

Go for the South West direction. That way when the band opens up, you can get some of the US. If using SSB go for horizontal, if FM the go for vertical.

If anyone is still following this thread.....an update.

I got my new Icom 706mk2g and High Sierra 1500 screwdriver about four days ago. A couple of hours working on the installation each day and I'm finally done. It works great!!! Got on tonight and the HS-1500 tunes easily from the driver's seat with an SWR of <1.2 on all bands. My first contact was with VK6APZ in Australia - he was beaming long path to the states! Good grief, I couldn't have asked for more!

I've got a pretty good ground in the mobile. I had an extra 20 feet of 1-1/2" copper strap from PolyPhaser and used it between the antenna and my steel frame about 6" away. I also used the copper strap to ground the radio, the hood, and trunk and applied anti-corrosive compound to all connections. The 706 faceplate is mounted neatly on the console and a cable runs to the radio mounted in the trunk. All wires and cables are hidden from view under carpet and inside plastic tubing for protection. I ordered a Clearspeech speaker but it's backordered for a couple weeks.

I'm getting a small amount of hash in my Honda Accord from the pair of engine fans that come on every few minutes while sitting in idle. Maybe I can filter them some way?

This is going to be fun!

73,
David, K4ZZR

If you can't get a rotor, mount the beam so you can turn it by hand. You'll want to be able to swing the antenna north for auroral propagation, and point in the appropriate directions for whatever sporadic-E or F2 propagation you might be able to take advantage of.

For my first year on 6m I used a hand-turned quad mounted about 15' off the ground. I worked 70 grids, 30 states and several provinces. Have fun, and don't forget to swing the beam my way once in a while. :-)

All the best,

Yep, I'm aware of the meaning of counsel, but since frac likes to play
Perry Mason I like to mess with his head.
>
> He's right, you are wrong. Now why not back off and give the guy a chance.
> On the evidence of the last week's postings he is obviously trying a new
> approach and surely deserves to be given another chance. How about a fresh
> start all round?

But I'm not wrong. The whole issue was his reply to W1RFI, in which he
stated that w1rfi's statement was incorrect, and that he that he should
consult counsel.

quote from W1RFI:
The number of public posts that you have made, Chip, suggest otherwise.
The
personal life that I am sure you lead that extends significantly past
the
content of your posts is not a news item, but the posts you have made
here
certainly are.

Frac says thats not true. W1RFI's statements were very correct. This is
a public forum, and if Frac is not the #1 poster I'll eat my hat. I'd
almost bet $$$ he's the "ALL TIME" #1 poster as far back as deja news
goes. If you post here , you are a public figure. I'm not trying to stir
up controversy, but the facts are facts. As far as the NG goes he is
very public. And I don't see any change in his approach at all. He's
right, the other person is wrong, and as usual needs counsel. It will
never change. I'm sorry now I even brought it up, but he provoked me
with his "your wrong, I'm always right, get counsel", attitude. I'm so
sick of his legal advice , I'm about to puke. If he had left counsel out
of it, I probably wouldn't have bothered with him. MK

Would it be a wiser choice to have the ground stake away from the concrete base? I would think that if the ground stake was under the base and attached to the rebar in the concrete, that if lightning hit the tower the current would be flowing through the rebar, heating the concrete till it exploded.

I hadn't seen your post before I posted the other one, but your experience seems to agree with my theory of this noise being streamer related. Or corona disharge, which in that case would be almost the same. I've also heard the noise that goes away with a lightning strike."usually a ticking type sound that varies with speed" That's what led me to believe I was hearing "streamers" off in distance. Maybe not too far away either. So maybe the best thing to kill noise, might not be a lighting rod, but maybe the opposite, a large blunt ball like a flag pole. Anyway, these theories make more sense to me than charged particles hitting the antenna. If that were true, I'd expect all levels to have about the same noise. MK

Cecil wrote:

> He
> has said that solid-state amplifiers can indeed eat enough reflected energy
> to overheat or blow themselves up. "Reflections II" will probably correct
> that misunderstanding.

This is not a good way to look at it. What happens is that the standing wave on the line causes the load impedance for the transistor to be the wrong value. This means that the collector/drain load impedance is not what is needed for proper efficiency. Suppose we want 100 W *net* power output. If this impedance is too low the transistor gets too hot. If the impedance is too high the transistor may not get too hot but the RF voltage on the collector/drain becomes too large and may destroy the transistor.

From a circuit standpoint this is what happens. The *circuit* behavior is affected by the *wave* behavior on the line.

A good technique, when thinking about RF systems, is to use the left side of the head to think "waves" and the right side of the head to think "circuit" and the middle of the head to see how the two sides are related and work together.

Basic principles.

>There probably are many stories of success and failure in the attempt to
>eliminate precipation static.
>
>Best regards, Richard Harrison, KB5WZI
>

Possible.
There are basically two problems with "precipitation static." One is a grounded or unchoked antenna acquiring static electricity charge and then arcing over to something. (That is easily solved with draining choke or resistors.) The second one is wideband noise caused by charged particles (snow, rain) hitting metallic things, having to discharge themselves and creating the hash, regardless of antenna, it shows up as about 20 over S9.
We had this happen during WRTC in Slovenia for about 8 hours, virtually paralyzing our reception. We were not allowed to have another antenna, even piece of wire lying on the ground.
It appears that this hash is caused by discharge of the droplets on metallic and grounded things, antenna then picks them up (it is right there in the middle of it). We had discussions on of the reflectors about the phenomena and mechanics of it (I forgot what was the conclusion, would have to look it up.)
The only 100% working solution seem to be, when you have stacked antennas, or two layers (high and low) of antennas, only the bottom ones are DEAD quiet, top or side positioned antennas are overwhelmed by hash.
Based on that experience I would guess that even having HV insulated wires way up there would pickup "signals" from the droplets being discharged on (metallic) things "up there." Maybe Laporte was playing with insulated rhombics on wooden poles? That would probably work, but metallic things in today's antennas are almost unavoidable, so I doubt that HV insulation would help, the hash is generated right inside of antenna. It didn't help with Razors, which I was trying to achieve and failed miserably :-)

Cecil, havn't you forgotten the time it takes for the 100 joules to be transported from the hydro-electric generators at Boulder to your shack ? ;o)

The question is "Where" does the reflected power go, not "When".

So we are not concerned with transients but with steady state.

So I repeat - all the RF power outputted by the transmitter is absorbed (for the want of a better word) by the antenna. THERE IS SIMPLY NOWHERE ELSE FOR IT TO GO.

Why unnecessarily complicate matters by dragging red herrings all over the place ? ;o)

It really depends on what you want to work, try having the main
lobe pointing down the east coast of Canada & the US where you should
be able to work a lot of stations when the band is open, and also if
you have poor front to back ratio you could work Auroral scatter from
the back of the beam (unlikely)
It really depends on how much you wish to monitor for those weaker
signals.

Hi Bill:

If you check my post again you will see that I made the following statement
:

"130 watts of power has an associated voltage magnitude of 80.623 V and a
current magnitude of 1.62 A."

So, I am not sure where the 0.62 A figure you quote comes from.

>
> 2) The forward power is 130 W. In terms of the forward wave this is
> (V+)^2 / 50, so (V+) = 80.62 V RMS

This is exactly as I have stated above.

> 3) The reflected power is 30 W. In terms of the reflected wave this is
> (V-)^2 / 50, so (V-) = 38.73 V RMS.

This is exactly as I have stated above.

>
> 4) The difference between the forward and reflected power waves is
> (V+)^2 / 50 - (V-)^2 /50 = 130 - 30 = 100 W.

This is true in all transmission line systems and is not a point of disagreement from my perspective. Regardless of the level of re-reflection at the transmitter, the net power delivered to the transmission line is always equal to the steady state forward power minus the steady state reflected power. It is important to understand that the 100 W of delivered power is a net value and not the forward source power of the transmitter. The point of issue is what power "components" combine to become the total steady state forward power of 130 watts. It is not a source power of 100 W "adding" to a re-reflected power of 30 W to become 130 W. The 100 watts is the effective net power delivered to the transmission line. The actual forward source power delivered to the transmission line is not 100 watts.

>

I agree with these statements. With the directional wattmeter, we are measuring steady state forward and reflected power in the transmission line. We are not measuring the true forward source power nor are we measuring the re-reflected power. All we can "see" with the wattmeter is the net forward power of 130 watts which is the result of the re-reflected power combining with the true forward source power. If these two powers are "in-phase", the 130 watts of total forward power will not be the result of 100 watts of true forward source power adding to 30 watts of re-reflected power.

IMHO, here's where the total power outputted by the transmitter goes (no
tuner between TX and antenna):

1) A portion of it is delivered to the antenna.
2) A portion of it is lost in the feedline
3) A portion of it is returned to the transmitter as a function of the
transmitter output impedance.

I agree. The misunderstanding arises because Walter Maxwell assumed a
tuner function with its accompanying Z0-match but he did not state his
assumption in words. Because he didn't state his assumption, some people
have inferred that he was talking about systems without a tuner. He wasn't.

That's what I said. The impedance seen depends on the phase of the reflections
that make it back to the transmitter.

Yep, that's what has happened to the venerable Kenwood TS940S/AT. I
have a pair of them in the closet, one that is pristine but has had a
lil' "static discharge" into its antenna port,(but the PLL's are alive)
and another thats pretty much a beater, but which does work, albeit with
a couple minor tribulations. Maybe this winter I'll get around to
combining the two into a really nice oldtimer.

Hey, a TS940 is old?????

But there is somewhere else for it to go, Reg. It is stored
in the transmission line until the transmitter is turned off.
This is easy to prove by observing TV signals with reflections
and the resultant ghosts. It is easy to prove that there is more
energy in the transmission line with reflections than without.

In my example where 300 joules is stored in the one second long
lossless transmission line, the transmission line continues to
deliver power to the load for many seconds after the transmitter
has been disconnected. 2/3 of that 300 joules is real live reflected
energy. It is really there. It is not imaginary.

We're talking about lossless systems, so number 2 doesn't apply.

We're talking about Z0-matched systems, so number 3 doesn't apply.

Cost of "one" 5/8" X 12" long drill bit for hammer drill is over $50
You'd probably want to go at least 18" if not 24. Depends on the rock. If
it's granite you'd need a diamond drill and they make the hammerdrill bits
look cheap.

Good hammer drill is $200 give or take.

I had one of the good industrial ones (5/8ths inch, not 1/2 inch, with 8 amp
motor) and it caught fire on the second day. (totaled it, but they replaced
it no questions asked)

You might be able to find one at a rental agency, but the drill bits could
get realy expensive.

It takes a really good set of shoulder and arm muscles to keep from getting
hurt when the thing hangs up. <:-))

I had an electrician friend get one hung up and the power cord pulled his
thumb out by the roots. Completely tore it off.

A lossless antenna tuner provides a Z0-match which doesn't allow any
reflected energy to reach the transmitter. The "SWR" between the transmitter
and the antenna tuner is 1:1. There is simply nowhere else for the reflected
energy to go except back towards the antenna. We know "what" happens from
a scalar standpoint. "How" is really not important except to academics.

I take it that these are the C3i antennas of the K1FO design.

A quick call to C3i will get you the figures you wish.

These sentences seem contradictory to me.

Cecil gave the formula for the inline wattmeter determined power early in this thread. It is:
forward power minus reflected power is the actual power at the measurement point. On a lossless line, power is the same at any point along the line, regardless of SWR. If the line is lossy, power measured at the load is less than that measured at the transmitter.

Re-reflected power and fresh from the transmitter power are indistinguishable to the wattmeter. So, the forward power indication can contain old power and fresh power.

If there is no significant loss, between the transmitter and its load, the power output of the transmitter and the power delivered to the load are the same quantity. Forward and reflected indicated powers should be the same at both ends of the transmission line. With loss in the line, the difference in net power indications at opposite ends of the transmission line is the power lost in the line.

Best regards, Richard Harrison, KB5WZI

2600. Re: Where does reflected power go?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-17 00:00:00 UTC
From: ehsjr@bellatlantic.net
Message-ID: <3A1556C6.C0BA47B2@bellatlantic.net>
Source record: 176246

Typically, with a good tuner, most of the power ends up radiated.
The amount of power that is lost (dissipated as heat, rather than
radiated) depends upon the loss figure of the transmission line
at the frequency of operation and the degree of mismatch between
the antenna and the transmission line. That is the simple answer.

An overview of the theory is below.
The power travels from the rig through the tuner trough the transmission
line to the antenna. Some of the power is dissipated (lost) as heat along
the way. When the power reaches the antenna, which has an impeadance
that does not match the transmission line impedance, some of it is radiated
by the antenna, and some of it is reflected back toward the tuner. On its
way back to the tuner, some of the reflected power is dissipated in the
transmission line. When it arrives at the tuner, it is re-reflected back
toward
the antenna. Again, part of that power is dissipated in the transmission
line
as it travels toward the antenna.

The amount (percentage) of arriving power that is reflected depends upon
the amount of mismatch; the amount of loss in the transmission line depends
on the type of line and the frequency.

Actually, Mr. Harrison alluded to it. His post was very good, in
my opinion. I added what I hope is a simple overview explanation of
what goes on. I hope it did not muddy the waters - and I would have
preferred that one of the experts had done it. I'm sure they can do a far
better job than I.

I really felt that for this particular question the overall basic description

was in question, not the more in depth stuff in the ensuing discussion. And
like you, I would have like to have seen a stronger mention of feedline loss.
Not that the discussion was out of place - it's always interesting what
these guys have to say! Just that the basics needed to be outlined first.

Hi Richard,

I'm not sure why. I think we all agree that there may be some level of re-reflection at the transmitter output and that this re-reflection adds to the transmitter's forward source power to become the total forward traveling power that we measure with a wattmeter. The effective net power delivered to the transmission line is the difference between the total forward and reflected powers. The transmitter's forward source power and the effective net power it delivers to the system are generally two different things.

Let's assume that we connect a transmitter to a TL connected to a matched load and we measure a forward traveling power of 100 watts and a reflected power of 0 watts. In this case, the net power delivered to the TL is 100 watts AND the transmitter's forward source power is also 100 watts.

Now let's change the load to 100 ohms. Numerous things could happen in this case to affect the forward and reflected powers in the TL.

One possibility is the following. We again measure a forward power of 100 watts and a reflected power of 11.11 watts. In this case, the transmitter's output impedance is ZO and again, no re-reflection occurs at the transmitter output. The 11.11 watts of reflected power is returned to the transmitter. The transmitter's forward source power is still 100 watts but the net power delivered to the TL system is only 88.89 watts.

Now, let's complicate the problem by creating the situation where re-reflections do occur at the transmitter output. Let's still assume that the transmitter delivers 100 watts of power to a matched load but that the transmitter's output impedance is no longer matched to ZO. Let's again assume that we change the load to 100 ohms. As one possibility, let's assume that we measure a forward power of 126.56 watts and a reflected power of 14.06 watts. The effective net power delivered to the TL is now 112.5 watts. However, the transmitter's forward source power still remains at 100 watts. Most people would immediately assume that the 126.56 watts of total forward power is the result of 14.06 watts of reflected power being totally re-reflected and then adding in-phase to the 112.5 watts of delivered power

such that 126.56 W = 112.5 W + 14.06 W. However, when we look at voltages and currents we see that in-phase power addition cannot occur in this manner. What really happens? In this case, my numbers were derived by assuming that the transmitter's output impedance was 100 ohms. Therefore, the actual re-reflected power is only 1.56 watts. This 1.56 watts of forward power "adds" to the transmitter's 100 watts of forward source power to become the total forward power of 126.56 watts. At this point, most people would say that 100 W + 1.56 Watts can't possibly equal 126.56 watts. So, let's check the "math" with voltage addition. 1.56 watts has a voltage magnitude of 8.83 V. 100 watts has a voltage magnitude of 70.71 V. These two voltages add to a total voltage magnitude of 79.54 V (they add in-phase) resulting in a total forward power of 126.56 W. In phase powers always add as Ptotal = P1 + P2 + 2 sqrt(P1) sqrt(P2).

Although it is always correct to determine effective net power delivery as follows: Net Power Delivery = Pforward - Preflected, it is incorrect to take this relationship and assume that Pforward is a result of Preflected being totally re-reflected and adding to Net Power Delivery such that Pforward = Net Power Delivery + Pre-reflected. On the surface it is not immediately obvious but these concepts are totally unrelated.

>

Correct, with the following understanding: From the TL's perspective, there are only two steady state powers. The forward traveling power and the reflected traveling power. The difference between the two is the "net power" delivered to the point where the measurements are made.

> Re-reflected power and fresh from the transmitter power are
> indistinguishable to the wattmeter. So, the forward power indication can
> contain old power and fresh power.
>

Correct.

> If there is no significant loss, between the transmitter and its load,
> the power output of the transmitter and the power delivered to the load
> are the same quantity.

This depends again on how we define the power output of the transmitter. Based on your statement, the "power output" of the transmitter would be defined as the "net power" delivered to the TL which is the difference between the forward and reflected power at the transmitter output. I have no problem with this definition except in the case where it is used to describe the relationship between total forward power and the re-reflected power at the transmitter output. The net power delivered to the TL is the

end result of the wave reflection and addition process, it is not the beginning of it. The re-reflected power "adds" to the transmitter's actual forward source power not the net power the transmitter "delivers". This is where the concepts start to mixed and used incorrectly.

Further thoughts to what I posted yesterday...

If you were to make the RG-217 35.5 electrical degrees long (about 1.45 meters, if I've calculated correctly, assuming velocity factor = 0.66), using a single 50 ohm line, and then put about 157pF of capacitance across the RF generator end of the line, the generator will "see" very close to a 50 ohm load, assuming the load on the other end of the line is 25 ohms resistive. In that case, the loss in the line will be roughly 8 watts per 1000 watts, or about 0.035dB. I'd say that's not enough to worry about, and if you don't have matching problems with your line 1/3 as long as that, the losses surely must be insignificant to you.

In summary: if the generator can deliver the power in your current situation (with a nominally 25 ohm load at the generator), there's probably no reason to hassle with doing it differently. If generator matching is a problem, you might improve things by making the line a bit longer and putting a capacitor (RF current rated!!) across the genertor end.

Cheers,
Tom

In my experience, and I have plenty with towers as tall as 300 feet,
the bulk of the noise comes from corona discharge.

If the antenna has rounded blunt edges that don't stick out into the
air, it is less affected by incliment weather.

I have problems with "rain static" even when the rain isn't here, just
because the voltage gradient between the antenna and sky increases.

I've found the same thing as Yuri, the only real cure is to mount the
antenna lower, so some other higher conductive object shields it, and
provides the discharge path into the air.

I even did an experiment, charging a water hose outlet with a very HV
supply, and spraying an "antenna" with a fog. The drops themselves
made no noise that I could detect, but getting the cloud near the
antenna end caused corona.

If you listen closely to rain staic (or snow static) during a storm,
you'll hear it build up into a high pitched high level peak, then when
lightning hits anywhere in the area it totally and immediately stops.
You also find that rain or snow MISSING the top antenna and stricking
the bottom antenna will NOT cause any noise at all in cases wher the
antenna is mounted lower on the tower. If the charges were in the
droplets, and transferred to the antenna by the contact...this would
clearly not be the case.

With the antenna tuner in-line between the antenna and the PA, none of the reflected power will arrive back at the PA, so this is not an issue.

Without getting into any physics, the SWR of the antenna does not change and as a result, there will still be reflected power on the line between the antenna and the tuner. With the tuner matched, there will be no reflected power between the tuner and the PA.

The reflected power from the antenna arrives at the tuner output where a portion of it is re-reflected back towards the antenna. As a result, there is more forward power in the line between the tuner and the antenna than in the line between the tuner and the PA. Therefore, more total power is delivered to the antenna for radiation than in the case where no tuner is used. The total power delivered to the antenna can never exceed the power delivered to the tuner. At the same time, since there is more forward and reflected power in the line than in the case where no tuner is used, the power dissipation in the transmission line increases. There will also be a small loss of power in the tuner.

The transmitter does not put more power into the feedline. The power that is reflected from the antenna is just now distributed differently in the system and more power is radiated by the antenna.

Ultimately, the reflected power from the antenna goes to three places:

1) A portion of it is re-delivered to the antenna.
2) A portion of it is lost in the transmission line.
3) A portion of it is returned to the tuner (this aspect of the discussion is complex and is beyond the scope of this response).

Hi Steve, All,

When the condition described above exists it is an acknowledgement
that there is a measurement plane between two planes of reflection.
Under such circumstances the Mismatch Uncertainty prevails and barring
knowledge of the phase of the components of the waves, any claims to
even poor accuracy of power determination are at best a dream.

A 2:1 mismatched source facing a 2:1 mismatched load will present an
uncertainty in power determination of 30% minimum - IN ADDITION TO ALL
OTHER INACCURACIES.

As such, further discussion of voltages and currents listed out to 2
decimal places of resolution are interesting, but hardly real.

Hi Richard:

The discussion were only meant to illustrate the concepts, which is where the real issues appear to be. As for the 2 decimal places, I only present them to avoid rounding errors if anyone wanted to verify the calculations. Whether the conditons described are real or not is secondary to the concepts discussed. Sorry for the trouble.

Steve

Yes Cecil, I checked umpteen months back as a matter of
routine. I forget the details but I couldn't find anything
the matter with Eznec. It does a sufficiently accurate job.

You can check yourself. Only takes a few seconds from
switching on the computer with Varney.exe. It takes weeks
to find a complete set of resonant frequencies just using
Eznec. But of course it is excellent at plotting radiation
patterns which none of my programs do.

I checked your original post again and it said 0.62 A. I corrected it in my reply to that post. Much ado about nothing, eh?

My recent replies to Cecil Moore and Bob Haviland have further opinions on this subject that I believe are OK.

Let's forget about waves and transmission lines for a moment, and connect a resistor directly to the output of the directional wattmeter. We will look at the *circuit*.

The directional wattmeter is an impedance bridge that is calibrated in watts for a Z0 ohm system. If the load is Z0 ohms the reflected port reads 0.0 W and the forward scale reads 100 watts. The bridge is *balanced*. The delivered power is 100 watts.

Suppose the reflected port reads 130watts and the forward port reads 30 watts. This means that there is an impedance difference between the load and the Z0 ohms that the bridge was designed for. In other words the readings of the meters are a somewhat indirect indication of the degree of the Z0 mismatch.

Consider a solid state broadband amplifier. If we want to, we might be able to deliver 100 watts to this resistor anyway. Crank up the amplifier until the difference between forward reading and reflected reading is 100 watts. Keep in mind that we are not talking about waves, but a *lumped* circuit.

The wattmeter makes two voltage measurements, one proportional to load current and one proportional to load voltage. These voltages are added at the forward port and subtracted at the reflected port. If the bridge is unbalanced then the load is not Z0, but we don't whether the load is less than Z0 or greater than Z0.

Now consider the amplifier. If the load is less than Z0 and we try to force 100 watts into it the amplifier may overheat. If the load is greater than Z0 and we try to force 100 watts, the transistors may be zapped by excessive collector/drain voltage. This has zero to do with waves, it has to do with the load impedance that the amplifier sees.

What I am suggesting is that the concepts of forward power and reflected power are really nothing more than a way of describing the degree of Z0 mismatch. The

actual power delivered is the product of the voltage across, and the current through, the load resistor. But this crazy directional wattmeter is calibrated in terms of a so-called "forward" power and a "reflected" power. The whole thing is just a game with words, *if* the load is a lumped impedance.

If we replace the lumped load with a Z0 coax and a distant load of some kind, the readings do tell us two values that we call forward and reflected power waves, from which we can find SWR. But the bottom line is that the bridge is in reality responding to the actual value of the impedance that the line presents to the wattmeter. This impedance is the result of the vector sum of forward and reflected voltage and current waves. The power numbers are "derived" from the voltage and current measurements.

We should keep in mind that voltage and current waves are the real entities that are being measured and that power is a "derived" unit, and not a basic entity that flows back and forth on the line. We have established this repeatedly in the past. The wattmeter responds to voltage and current, and not "directly" to watts. And that is why the question "where does the reflected power go?" is moot. The power doesn't go anywhere, it is voltage and current that travel, and power is merely a "value" that goes along for the ride.

And the crucial parameter for the broadband solid state amplifier is its complex load impedance, which can cause mayhem.

The dope is a substance used for copper to aluminum connections. It's available under many different names from any place that sells electrical supplies including Home Depot. I would't worry about your wire underground. Aluminum came from there in the first place and it should outlast either one of us. 73

Hi Steve,

My point was not so much the reported values, but that those values
were meaningless even conceptually.

When the measurement plane falls between two planes of reflection,
even for modest mismatches (2:1) there is so much error injected into
the debate as to render it useless.

Also, this is not a problem of Trouble, per sï¿½, but rather a learning
opportunity as to the nature of Power determination and sources of
error. Conceptually every discussion point attempted here would be
well served if all such reportings of current and voltage were in
phasor form.

There is no mandate that this argument be devoid of the data necessary
to conduct the debate. Relying on simple SWR reporting fails in this
regard, but the scenario may be recovered by simply (and arbitrarily)
introducing the phase back into the discussion.

I would agree that the real parameters to consider in this discussion are the traveling voltage and current. They are the quantities that must be considered to understand wave behavior and the relationships between the forward and reflected waves in the TL. In any measurement or analysis, power is always the derived quantity. I would like to continue the discussion as it relates to the complex "load impedance" and your comments above:

"If the load is less than Z0 and we try to force 100 watts into it the amplifier may overheat. If the load is greater than Z0 and we try to force 100 watts, the transistors may be zapped by excessive collector/drain voltage. This has zero to do with waves, it has to do with the load impedance that the amplifier sees."

In the transmission line problem, the load impedance the amplifier "sees" has everything to do with the waves traveling in the TL. The only impedance that the amplifier ever "sees" is the transmission line characteristic impedance Z0. It never really ever "sees" any other physical impedance. From the perspective of your discussion above, just like power, the steady state load or line impedance at the amplifier output is a derived quantity

and it too is a function of the traveling voltages and currents. Consider first that the amplifier drives the TL with a forward source voltage and current that is entirely a function of ZO. At the amplifier output, there will also be a rearward traveling reflected voltage and current and, if the amplifier output impedance is not equal to ZO, there will also be a forward traveling re-reflected voltage and current. The total voltage developed at the amplifier output is equal to Vsource + Vreflected + Vre-reflected. The total current developed at the amplifier output is equal to Isource - Ireflected + Ire-reflected (the + and - sign with current is a function of the math convention selected for the analysis). The effective load or line impedance is simply derived from Vtotal / Itotal. The steady state power delivered to this effective impedance is in fact the steady state power delivered to the TL and is found from Pdel = |Vtotal| |Itotal| cos (theta), where theta is the phase angle between Vtotal and Itotal. We also know that in all cases, Vforward total is equal to Vsource + Vre-reflected.

From the perspective of the internal components in the amplifier, there are two "sources" in the system. One is the internal amplifier forward driving source and the other is the rearward driving source created from the reflections that arrive at the amplifier output. In all cases, except where the amplifier has a purely reactive output impedance, some level of voltage and current travel rearward into the amplifier. The level of voltage delivered rearward into the amplifier is equal to Vreflected + Vre-reflected. The total steady state voltages developed within the amplifier are the combination of the forward voltage developed within the amplifier and the rearward voltage developed within the amplifier. Since the forward and rearward voltages are traveling in opposite directions, the total voltage developed in any one series component is equal to Vforward - Vrearward. The total voltage developed in anyone parallel component is equal to Vforward + Vrearward.

The total power dissipation occurring within the amplifier is a function of both the amplifier's forward source and the wave reflections within the system. If the wave reflections and re-reflections are such that the effective load impedance is less than ZO, Vforward and Vrearward typically combine to increase the total voltages within the amplifier such that more power is dissipated in the amplifier relative to the situation where the amplifier operates into a matched load.

The load impedance "seen" by the amplifier is a direct function of the forward and reflected waves within the transmission line. Given that the internal power dissipation within the amplifier is a function of this load impedance, it must follow that the internal power dissipation is a function of the reflected waves traveling within the system. For this reason, reflected waves are quite real and are significant as to how the voltages and currents develop within any system component. They cannot be ignored as if they don't really exist.

Source record: 176265

Let me see if people with a better brain than I can figure this out....

I thought I would stick up a quick and dirty 40M dipole fed with 450 Ohm ladderline to an MFJ941C tuner. I bought the tuner used six months ago but had never got around to using it. The ladder line is brand new.

I have made many dipoles before over the years with no major problems. So I was quite surprised , when I got the thing up in the air (only 20 feet at this point) , that the receive was VERY bad. I have not even tried to xmit on the antenna yet. I checked the ladder line connection to the antenna and all appears to be okay. Receiving WWV on 10 and 15 MHz my existing G5RV gets an S9 usually, this new dipole gets an S1 to S2 regardless of settings on the 941C. I double checked the short coax cable between the rig and 941C and it too appears okay. Just for the fun of it, I took the ladderline our of the 941C , stuck one end of the ladder line into my coax connector on my rig, when I do that the receive on WWV increases to S7. Also when I connected my existing G5RV via the 941C it works fine.

So, I am baffled as to why when I connect both side of the ladder line with an antenna connected to it via the 941C that I get S1 to S2.

Any thoughts?????

Andy KB2EOQ

Source record: 176266

Cecil, further to my last message -

I've just compared your analysis of the 'standard' G5RV in
your latest web site with results using VARNEY.exe

Comparison between two large masses of figures are more
confusing than helpful. So I will summarise the input
impedance data, R+jX, for the 102 feet dipole (no feeder)
in the following manner.

Using VARNEY, slightly deviate frequency until either my R
or jX agrees exactly with your R or jX, then the following
table results -

F MHz	Dev %
3.8	0.9
7.2	-0.8
10.125	1.1
14.2	-1.3
18.14	-0.2
21.3	0.0
24.95	-1.0
28.4	0.0

The small frequency deviations needed are most likely due to
me having to guess at the type of ground and antenna
conductor diameter.

The following table compares your values of SWR on the 50
ohm line, obtained using EZNEC and the ARRL transmission
line calculator, with my values of SWR using VARNEY. I had
to guess at the feeder attenuation. The ARRL and EZNEC
probably ignore it.

FMHz	Your SWR	My SWR
3.8	3.4	2.2
7.2	4.3	5.5
10.125	50	56
14.2	2.6	2.7
18.14	40	39
21.3	7.8	7.3
24.95	2.2	2.2
28.4	64	71

I would judge that the differences between the computer programs are no worse than the accuracy of the data which is likely to be fed into them.

The following is a table of resonant frequencies and the 50-ohm SWR for the standard G5RV with a 450-ohm ladder line which is 1/2-wave long at 14.15 MHz.

Res Freq. SWR-50
---------- ----------
3.566 2.1
7.945 1.5
14.145 2.2
20.370 1.2
24.736 2.0
32.053 1.5

Although only 2 resonant frequencies lie in amateur bands, the low average value of SWR at resonance shows the superiority of 450-ohm line in that respect. This sort of table can be generated in a few minutes using Varney.exe

And I've just noticed my G5RV is about 12 inches longer than yours ! Which should be added to the list of differences in computer input data.

I used bare aluminum wire for my sixty radials here in N. Texas several years ago. Within about six months most of the radials were gone due to the alkaline nature of our soil here. I replaced all of the aluminum radials (what was left) with insulated wire. 73, Ed - N5NUG

I think that there is a jumper that must be connected in order to put
the internal balun in the circuit. I don't have a '941 tuner here, but I
have two others and they both require the jumper. Look on the back for
an indication of a "wire" between two posts. Connect the wire and try
again.

Good luck and 73, CJ K0CJ

Hi folks,

so - with all the experts here:

What is the big difference between:

A - A built in Tuner like in a FT1000 etc. that 'matches' up to a SWR of
1:3
B - A external autotuner like the Kenwood AT250, the Yaesu FC-1000 etc.
C - The all famous SGC - Antenna coupler.

Many thanks in advance,

73,
Peter

Don't work!
When I designed Razor Beams, I used insulated wire for quad elements and all yagi elements were "grounded" to the boom and tower, all at the ground potential (DC). When rain or snow static came, there was that 20 over S9 hash on the top antenna. Same as on "crumy" TH6. But when I switched to bottom one, it was dead silence (form static hash). They were both "grounded" on the same tower.
It appears that top antenna acts as an umbrella for static charge. That was the only way I could "ignore" the rain/snow static.
When talking about discharge from static electricity buildup, of course you need things grounded directly or via chokes/resistors/stubs.

I'll be dipped. Not a word from the experts about low loss feedline
preserving more of the power for radiation rather than dissipation,
whether or not we're talking of the forward incident wave or a reflected
wave.

In general, external tuners are more robust and can tolerate higher
voltages and currents, as well as handling higher SWR situations than
interna; tuners.

Internal tuners are noted for being relatively "tender" and easily
damaged by voltage/current extremes.

Extending the story of my years with the Highway Patrol to this
subject, on occasion we would find a ham working CW on the 40 meter band
interfering with one of the several receivers we continuously monitored
in the 42 mHz range, from the 6th harmonic of his signal. You'd be
surprised how little radiated energy it takes to open the squelch on a
sensitive FM receiver. I soon learned to keep a ham callbook in the
drawer so that I could quickly find who the culprit was and get him on
the phone. To copy his callsign, I'd just openthe squelch on the
receiver he was hitting and capy the noise quieting. Worked quite well,
until we moved to a new building with newly installed equipment which
had NO consolemounted squelch controls. All you could hear would be a
"thumppity, thump thump" sound which was not possible to copy as Morse
code. I soon learned to take a walkie talkie or a signal generator and
provide a beat note.
I don't know what they do nowdays. There's no one left there who can
copy CW. But maybe they don't have such interference these days due to
lessened activity on 40 CW.
At one time early on I lived a couple blocks from the station, and a
couple of times *I* got the call, while beeping at home on 40, and soon
learned to carefully avoid a couple of particular discrete frequencies
there.
Since we used a number of remote talk-in repeaters as well as the
local receivers, there was a lot of opportunity for this sort of
interference over all of the state. At that, it didn't happen often.

> where a reflected wave acts?
>

I don't know what happens elsewhere, but here's how it goes at my
station.
When I transmit through my tuner then through the coax feeding my
antenna, if I'm on a frequency where the antenna is perfectly matched to
the feedline, and the tuner is then matched to both the feedline at its
output, and to the transmitter at its input, there is no reflected wave
present. SWR can be said to be 1:1 both between the transmitter and the
tuner, between the tuner and the feedline and the antenna.

When I move off the resonant frequency of my antenna, there then exists
a reflected wave component that returns from the antenna through the
coaxial feedline to the tuner. After a slight readjustment of the tuner,
there then exists no reflected wave between the transmitter and the
tuner, but there still exists a reflected wave component travelling back
and forth between the tuner and the antenna on the coaxial feedline.

Where does reflected "power" go? That part that successfully travels
back and forth between the tuner and the antenna and reaches the antenna
again (the entire reflected component less that amount that is
dissipated as heat due to line loss) is radiated as RF energy into space
- except that amount that is again re-reflected because of the mismatch
existing at the coax/antenna junction. It makes the trip again, and once
again suffers the lossikntroduced by the feedline loss characteristic.

So it goes, back and forth, with most of the original RF that enters
the feedline being radiated by the antenna and some small amount being
reflected, re-reflected and partly radiated, and so on for as long as
the transmitter is keyed, assuming some acceptable level of SWR that
doesn't create too much loss or cause voltages too high for the coax to
tolerate.

The bottom line here is that you can construct a dipole antenna for the center of any HF band, then using a tuner located at the tranmitter, operate with perfectly acceptable reflected wave level and no detectable degernation of service on either end of the RF circuit. I use parallelled dipoles for multiple band operation.

By now it should be obvious where some of the pitfalls of this system lie. Since most coaxial line exhibits loss at high SWR, and high voltages can exist at those high reflected levels, it behoove one to use a good quality coax selected for good high voltage rating and low loss. Since coax loss increases with frequency, and this factor becomes much worse above HF, one has less latitude with such installations at VHF and above than at HF. Many hams prefer to use balanced open wire or ladder line feedlines which have much lower loss than coax, and which then can be used at much higher SWR than coax. There are some advantages to this approach but it is more restrictive from a hardware standpoint than simple coaxial line intallations.

Dick W0EX

2635. 6m Beam Direction

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-17 03:25:54 UTC
From: Peter <ve9ptr@hotmail.com>
Message-ID: <6z1R5.3953$rm4.82874@sodalite.nbnet.nb.ca>
Source record: 176317
Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna

I'm wondering what would be the best direction to point a 6m beam? I do not have a rotor available at this time. My location is on the east coast of Canada (grid FN65) and am very new to 6m. In fact, this will be my first antenna for this band!

Peter

2636. G5RV Misteries unraveled at last.

Newsgroup: rec.radio.amateur.antenna

Source record: 176219

Computer program VARNEY.exe is now available:

Entertain yourself!

It models:-

Tuner+
Coax+
Balun+
BalancedLine+
Dipole&
Ground.

If you don't need the coax or the twin line just set the
appropriate length to zero.

Enter details/dimensions of each component in the system.

Obtain input impedance R+jX (as measured on your antenna
analyser) of each component, transmission efficiency, swr,
etc. Then overall efficiency.

Plus L-network tuner L and C component values. Also which
end to connect the capacitor. Or is no capacitor required ?

Vary frequency from 1.5 to 35 MHz. Vary coax length and Zo,
balanced line length and Zo, dipole length and height,
balun ratio.

Find those elusive resonant frequencies in a few seconds.
Even the ones which are not of much use. Special on-screen
facilities to assist the user to find resonances.

Force resonance and low swr at any frequency by varing line
lengths and/or Zo. Find optimum Zo for mult-band working.
If there is one.

Just watch the tuner micro-henrys and picofarads whizzing
round as you vary the feeder length.

Avoid inconvenient component values in the tuner.

Which way round should you connect the tuner ?

Can you make the tuner redundant on your favourite band. ?

How long must the coax be to render the tuner unnecessary ?
;o)

Check the swr bandwidth. But in fact there's no need to know any swr's - the impedance R+jX actually presented to the transmitter without the tuner is continuously available.

For the G5RV admirer, enter Louis' full set of antenna data ready for analysis by hitting a single key. Depart from the specification and immediately see the results.

Educate yourself on dipole behaviour. Do some indoor armchair experimenting while the weather is bad. When the sun comes out go into your back yard and start erecting with confidence and vigour.

Download VARNEY.exe in a few seconds. Not zipped-up. Run immediately. Read operating notes and off you go!

When I put up my vertical I installed 60 radials. I used the Home Depot
17 ga aluminum wire.

That was 3 years ago, and now I am beginning to worry about the
condition of the radials from the viewpoint of corrosion due to soil
conditions, etc. The radials are below the sod about an inch. I could
dig up one and look but various health problems over the last 3 years
have prevented that.

So, my question: has anyone else used the aluminum wire for radials, and
if so, how well do they stand up under shallow burial?

Steve, what is the "dope" you smeared on the connections?

Thanks.

72/73, George W5YR - the Yellow Rose of Texas NETXQRP 6
Fairview, TX 30 mi NE Dallas in Collin county QRP-L 1373
Amateur Radio W5YR, in the 55th year and it just keeps getting better!

Reg,
Speaking only for myself, I'm one of those "nutters" that is simply
trying to understand how things work from the point of view of waves
(voltage and current waves, not power). This may not be necessary
when designing and building things, but it is educational, and that's
the point. Sorry you don't want to participate.

> Y'know?

Yep, now -thanks to you- I know. I've already got the guy cable, and if I can still climb that thing next spring your advice will be followed. Now I understand the dynamic forces that come to play on the installation.

Fact is I have only a medium size tribander just above the tower top, with a single 2meter 11-eleven element and a 5/8 wave 2m GP, all on an 8ft mast. I've been thinking about replacing all that anyway, so next spring looks like the time.
Tnx, Brian.

Mark Keith wrote:
"Anyway, these theories make more sense to me than charged particles hitting the antenna."

Terman agrees:
"The term "precipitation static" denotes a type of interference frequently observed in an airplane passing through snow or rain. Under such circumstances, the airplane may become electrostatically charged to such a high potential with respect to the surrounding space that a corona discharge breaks out at some sharp point on the plane. The interference that this corona discharge produces with radio reception, termed "precipitation static" is particularly serious at short-wave and lower frequencies.

Precipitation static can be minimized by the use of antennas that are either insulated wires or shielded loops, by equipping the plane with dischargers that provide a noninterfering means of getting rid of the charge being acquired by the plane, and locating receiving antennas as far as possible from the corona discharges."

Let's see now, you're saying that the antenna tuner passes ALL power going from the transmitter toward the antenna. It would have to since you've already said that the SWR is 1:1. You're also saying that the antenna tuner passes NO power going from the antenna back toward the transmitter. In your description, the tuner has to be a non-reciprocal device. It just doesn't make sense for a tuner to treat incident waves differently only because they're going different directions.

> We know "what" happens from a scalar standpoint. "How" is really not
> important except to academics.

Not true. "How" is really important if you should try to explain what happens to a novice who is trying to reconcile your description with standard theory concepts like reciprocity.

Why is the motor generating has? Is this a DC motor with brushes? If AC,
is should run
"clean" once started.

You also need to determine how the noise is being propagated. Chances are
that simply using
a 1/4-wave coaxial stub across the line will become a common-mode 1/4-wave
radiator and
worsen the problem. You best bet is bypassing both power leads directly to
the motor case,
with shortest possible leads. This presents a problem, since your bypass
caps will need to be

UL rated for AC linepass service. You could also try using parallel
resonant circuits in series
with each of the power leads at motor case. Considering the proximity of
the receiver, it will
be very difficult to fully eliminate the noise.

A quarter wave stub on each side of the line might work, but you definately
need something more
substantial than RG-174. I would think teflon coax would be best, but that
still leaves some
safey issues in my mind.

Pete

I've been kicking this around in my head. I think a lightning rod would cure it. I thought about the ball or ball discharger as some call them, but seems to me if the antenna streams ok as is, I don't really see how using a ball in the area would help much except for the tower or mast it was attached to. It would keep the tower from easily streaming, but don't think it would keep the antenna from streaming if it would be inclined to do it anyway. I thought about possible noise from the arcing of a streamer itself, and maybe that would make things worse, but if you can have the bottom antenna quiet while the top is streaming, seems to me you could be fairly close to a "designed streamer" and not have too bad a noise. So I kind of think adding a lightning rod above the top antenna would help a lot. The rod would stream much easier than the top antenna and would be above it a bit. This should "act" as another antenna above the top one, and make both quiet. I can't try it here, as don't even have one layer of beam up, much less two, but might be worth a try for someone who does. MK

I think they have the same attorney. I notice now he wants a rematch on 10m. What happened last time? I tuned and tuned and tuned again last time with not a peep. I don't see how I could have missed him being as he should have had a signal strong enough to peel paint according to his description. My old TS-830 works to utter perfection, so doubt that was a problem. Also I was listening for any AMEX types that talk 22,056 wpm. Heard a few, some even in 1 land, but no chirps from chip. I guess when the big Dodge City gunfight was going on, he was ducking in at the long branch. MK

You`re on to something. The tuner is behaving as a bidirectional
transformer.

The tuner may transform whatever load it feeds, say 20 ohms or 200 ohms,
to 50 ohms so that standing waves (sorry Reg) are minimized on the coax
connecting the tuner and the radio. The radio should then behave as it
was designed.

Who knows what the radio output impedance is or needs to know what the
radio output impedance is? Or, do you think we have a conjugate match or
need a conjugate match with the radio? This might affect re-reflection.

Best regards, Richard Harrison, KB5WZI

Lee Smith wrote:
"I would appreciate your assistance in developing a formula to present to the building owners which is fair to both sides of the negotiation process."

Tower space is worth whatever the market will pay. You need more than space for your antenna. You probably need air conditioned equipment space, access, power, and other accommodiations. You also need not to trouble or be troubled by each other and others around you.

You need renewal options which won`t price you out while you would like to stay. You also want to be able to get out when you do want to move, without too much penalty. New construction can block too much of your coverage, or other big problems can appear. We had one of our broadcasters claim that our air conditioning equipment was corroding his antenna. He really just wanted out of his lease.

What use you make of your accommodations probably won`t affect what you have to pay. What you pay usually depends on what revenue your lease space can bring a lessee. In a larger market you can expect to pay more.

So, you should survey the price paid for what you want in similar market areas if there is no data for your area.

I worked for a corporation that leased accommodations to FM broadcasters atop its company headquarters. We also leased space for our operations all over the USA. Abroad we mostly bought the property we used. There are likely tower rental companies in or around your area which have standard contracts and schedules of prices and accommodations. Ask for their contracts and prices, or tell them what you need and ask for quotations.

Best regards, Richard Harrison, KB5WZI

> differently only because they're going different directions.

The generated energy and the reflected energy indeed do see different conditions because part of what the generated energy sees is the reflected energy and part of what the reflected energy sees is the generated energy.

A transformer treats reflected energy differently from generated energy. It steps one up and the other down. Why can't an antenna tuner treat the two signals differently?

There is only generated power into the tuner input. There is forward power out of and reflected power into the tuner output. Forward power out of the tuner equals generated power into the tuner plus reflected power into the tuner. Conservation of energy indeed does make sense. With a Z0-match in a lossless system, there is simply no place else for the reflected energy to go except back towards the antenna.

Source record: 176089

I travel in a 35 foot motorhome with a rubber roof. I currently use a verticle Outbacker Perth into an Icom 725.

I would like to see a design that would allow me to built a horizontal dipole by laying iton the roof. Maybe epoxyed down and fed from two directions (end, side) to give some directionability.

Obviously I would need multiband options 10/80 using tuning coils. I want to be able to do this with the least amount of intrusion into the motorhome.

Any help would be appreciated. 73

Simply illustrating a small nit...
Every two seconds (when the next "wave" of reflections arrives from
the antenna end of the xmission line), you'll have to readjust your
tuner for a Z0 match until, many seconds later, you finally reach
steady state.

Abuse is wrong!

However, I don't understand your argument with respect to Sidis vs. New Yorker. This case refers to the boy genius who burned out at Harvard...if memory serves me. No disrespect Dr. Cohen, I just need additional information about the case you referenced to better understand the privacy protection we all deserve.

All I have is:

Sidis vs. F-R Pub. Corp
Federal Reporter, 1941, #113, 807-811

In a 5 - 4 opinion, hence by a single vote, the US Supreme Court decided that when fame is cast upon one's shoulders, that person shoulders the burden of losing one's rights of privacy. Chief Justice Brandeis, the deciding vote, said The New Yorker article was, "...merciless in its dissection of intimate details of its subject's life," and further admitted that ALL have the "... right to be protected from the prying of the press..." But he proceeded to deny Sidis that right because he was a public figure! This case set the precedent which has come up time and again in celebrity libel cases against the press.

Thanks,
Julie

I am not surprised that you do not understand it. But frankly I did not pose this as a source for speculation and efforts to misunderstand. In fact, I did not find nor study it myself. Nor am I sufficiently informed to comment upon it myself.

My point is that the homework is done: I am not a public figure, and that even 'borderline' public figures can successfully sue for malicious libel, of which this NG has abounded.

So before we have Mr. Keith wallowing in a sea of MORE malicious libel, it seems in his best interest that he respect the privacy and decency of others. And if you take exception to that, then please leave me out of said discussion.

Thank you.

Cordially,

NC

Yes; as I said.

Here's what I do to assure braid continuity at the feed over a long period of time:

1) solder the braid as well as I can;
2) use copper tape to sheath the braid and connector;
3) cover with a second sheath of coax seal or good electrical tape. Or, better

yet, shrink wrap.

Water is an absolute killer of coax! How it gets in is beyond my ken, but I've seen oxidation 20 feet in sometimes.

I just replaced some coax after only 2 1/2 years. Its insidious too, because often times, with the braid connected, the oxidation adds to ohmic loss and can actually improve the SWR in some cases--while cutting back gain (slightly).

But I am sure there are others with worse coax war stories.

Best of luck on the antenna!

My points on thesew issues have been made.

Now: I reiterate my challenge to you in the upcoming 10M contest.

I submit that i will beat you handily, using the 10m FQY described on the ham page of:

http://www.fractenna.com

As I have demonstrated, in recent weeks, the ability and viability of making the claim that I can and will beat you--witness my 350 plus an hour QSO rates during NON contest periods-- you should either accept the challenge or gve a compelling reason why you cannot do so.

The FQY is a superior performance Yagi for its size. That antenna, and my operating skills, will easily beat any effort (in this contest) you make with far larger and higher antennas at the same power.

Expecting your constructive competition,

73

Hi, 'Julie', 'Yuri':

Hmmm .. so, then, defining 'abuse' apparently depends on the resources allocable to hiring practitioners from the priestcraft which depends on a dead language to make and say things which have the force of law, the translations of which into the vernacular make only occasional sense to ordinary men .. ?!

God Himself needed only a couple of stone tablets. Then came the priests ..

Hmmm .. one set of priests creates the 'laws' for us fools, another set of priests administers them to us fools, and a third set defends us luckless fools from the depredations of the first two sets, in the process making yet another body of 'law', and impoverishing us all the while. Another problem for us luckless fools is that the defender-priestcraft and the other two sets are joined at the hip, with all that that implies. What a potentially incestuous 'love triangle'.

I notice, in the response from the Bombast of Belmont, that he considers himself competent to cite some priestcraftly wizardry as supporting his position, and then proclaims himself incompetent to pronounce on the putative relevance of the cite. He retreats to 'homework done' status, an uncharacteristically inferior, subordinate position for him. That's what they all say, 'The homework's done', before entering the courthouse classroom, where, on occasion, the opposing 'priest' feeds the 'homework' to the obliging dogs.

There are circumstances, the reality of which we do not need 'peers' or a 'priest' to persuade or adjudicate for us. I submit as Exhibit 1, that deja's public record of around four thousand r.r.a.a off- and on-topic posts, since 5/15/99, from the 'FRACTENNA' entity, do not qualify said entity for, or contribute to, the obscurity it claims to seek, and so richly deserves to find.

Obscurity abounds at this entity's website, and probably chafes.

We have here the spectacle of an entity making 4000 public posts, some of which claimed that anti-semitism and Nazi-ism are rife here, and then invoking 'privacy' as a protection against disagreeable responses to those and other posts.

Render BUBBA, Belmont's Unparalleled Bafflegab-er, BA, the privacy he so publicly and plaintively covets:

DO NOT ANSWER F-WORD TROLLS.

Hello All:

I am in the process of negotiating a lease to place a two bay circular polarized FM broadcast antenna on the roof of a building which is 450 feet high in the centre of the city and need your help in determining a fair monthly rental rate.

The station is an Adult Standards music format, aimed at persons aged 45+ and the transmitter will operate at 1 Kw. As with any new business, the first 3 years are very critical with respect to profitability.

I will not have exclusivity, and there will be no revenue competition for other services by adding highspeed Internet, paging services, trunk communications, etc.

I would appreciate your assistance in developing a formula to present to the building owners which is fair to both sides of the negotiation process.

Please reply either via the newsgroup, or direct email to lee@ckvn.com

Thank-you for the help.
Lee Smith

>
Might have been some additional nasties at work. You indicated in an earlier post that the tower was swaying before it flopped over. Might be that with all that ice there could have been a big inertial "flywheel effect" in play in addition to the straight-in wind load. Basically the tower was fighting the swaying but the weight of the ice simply overstressed a leg at the base during the terminal rotation. These sorts of considerations move the matter into the realm of dynamic mechanics, vibrations and material fatigue which becomes a whole new rat's nest. In the end you probably had a combination of sources of stresses at work. The weight of the tower itself, the weight of the ice, the static wind load and a cyclic rotational dynamic load. They all added together at a critical moment and over she went.

When you get into tornados all bets are off, you forget the book, run like hell and pray. Some time when you get to downtown St. Louis check out what's left of their ancient monster radio tower. A tornado blew most of the thing over I think sometime in the 30s or 40s and dropped it thru an apartment building and killed something like 14 people.

>
The grunt engineer can run the numbers and via straight up physics design a tower which has a specific failure load and expected life. From there it gets "overdesigned" by it's chosen design safety factor which is some number like 2X, 4X, 10X etc. It basically gets down to management decisions on risk vs. cost, tower industry design standards, building codes and lawyers and fear thereof. None of which have much if anything to do with the physics. I'm not in that biz but I'll guess they get overdesigned by somewhere around 500%.

>
It depends on how big your antennas are and I have no clue. But for discussion puposes I'll assume a healthy stack of HF beams on a longish mast which is to say a decent wind load. Visualize how the tower will bend in a heavy wind. The base ain't going anywhere. The point at which the tower is guyed ain't going nowhere, either. But given enough wind on the antennas the tower will rotate with the guy point acting as the upper pivot

point. It'll bend outward into the wind in an arc with the point of maximum lateral deflection being around the midpoint between the guy bracket and the base. This could set up a really nasty potential column failure scenario. The guys will impose their compression load on a long skinny bent column. It's a double-whammy because the more you bend a column the weaker it becomes at a huge rate, it gets many times weaker per pound of compression load the more the tower gets bent and you can get into a runaway situation.
>
The fact that your guys are ten feet down from the top is not necessarily in the right direction. That configuration definitely increases the "leverage" the wind has for bending your tower. There's an optimum guy bracket location which could be determined by a lot of numerical engineery pushups and it could just be that the 50ft level ain't even close to where it should be guyed.
>
The purpose of the center set of guys is to prevent the tower from bending in the first place thus completely eliminating the prospect of a column bending failure. A straight tower can take many time more times downward guy-induced compression load than it can when it's a bent tower. In your particular case your tower might be plenty stiff enough for it's loading conditions and won't bend enough to be concerned about not having the second set of guys. Ya hafta get really specific about the numbers before any real-world conclusions can be drawn.
>
Gets back to the Rohn specs: If Rohn sez guys every 30 ft just do guys every 30 ft. Y'know?

EHS, Jr. wrote:
"And like you, I would have liked to seen a stronger mention of feedline loss."

A perfect r-f transmission line has uniformly distributed series inductance and shunt capacitance. These reactive characteristics store energy per unit length. When r-f sets out on its journey through the line it is slightly retarded in velocity by the time needed to get current flowing through the line`s series inductance and to get voltage across the line`s shunt capacitance charged up to the applied voltage. It takes more time for r-f to flow through a transmission line than through free space.

There is energy stored in the line. When a transmitter stops, r-f continues flowing from the transmission line for the short while required to empty the line.

A perfect transmission line has no resistance in its conductors and no leakage conductance. Paradoxically, the ideal line having no series resistance and no shunt conductance has a current flow which is exactly in phase with the voltage across the transmission line.

Any loss in the line produces some phase shift from the pure resistive in-phase relation of an ideal line. Nothing is perfect, but most transmission lines are good enough for practical purposes. The characteristic impedance (surge impedance) , or Zo is a resistance, but not a resistor which consumes power.

Zo is called a surge impedance because any burst of energy applied to the line is forced by the line`s construction to conform to the voltage to current ratio dicted by that construstion. If we put 100 volts across a Zo of 50 ohms, 2 amps flows, unless and until an energy reflection comes back to alter the apparent impedance of the line. Obviously, if a line were infinitely long, no reflection could return.

If a real resistor equal to the Zo is placed across the far end of a transmission line, all energy is accepted from the line. So, none returns as a reflection to produce an impedance on the line other than Zo. If a reactance, or resistance other than Zo, terminates the transmission line it can`t absorb all the energy the transmission line is able to povide, so some or all of the traveling energy is reflected.

The cyclical energy traveling toward the load, and the part reflected, produce an SWR pattern on the transmission line, given the mismatch and enough line to show a pattern. The varying phase in a long enough line produces a repeating pattern of a wide range of complex impedances as

indicated by SWR.

High impedance is shown by voltage maxima. Low impedance is shown by current maxima. These are 90 degrees apart in a line.

A circle diagram or Smith chart can be used to determine the impedance at any point on a mismatched line. All the values fall on a VSWR circle on the chart if line loss is negligible. We need to know the load impedance and the characteristic impedance of the line to use a chart.

The rub is that the charts used to show impedance at any point are far easier to use by assuming lossless transmission line, so that will be the usual starting place.

Best regards, Richard Harrison, KB5WZI

Ah. Act like an expert on the subject until a *real* one shows up, then
plead ignorance. Typical.

Might as well do that with antennas, too.

When I installed my base (3x3x3ft)I first dug the hole then drove
several 2ft steel rods into the sides of the empty hole, so that the
earth was effectively tied to the concrete after it was poured. This
effectively gives you the ground surrounding the base as a part of it.

I'd be suspicious of the balun in the tuner, it may be either bad or
miswired.

Does that tuner require the "jumper" wire to enable the balun? If it
does and the wire isn't connected it won't work right.

Dick

Peter,
You really need to be able to turn it, or you defeat the purpose of having a beam. If a rotator is not a possibility, mount it on a piece of pipe fastened to the side of the house or garage, loose enough that you can turn it by hand. For skip propagation, height is not a big deal; A 6 m beam at 20 feet has the same takeoff angle as a 20 meter beam at 72 feet. I have talked to numerous W0s and 9s who had their antenna at 15 feet - but pointed this way. Regardless of which way you point it, you will be able to work some stations off the back, but not off the side.

I'll second the motion. I use the 941 and have never had a problem. A jumper is required between the "Wire" terminal and the nearest of the two "Balanced Line" terminal.
Lots of luck!

It doesn't, I had Ringo ranger 2m vertical, which is basically grounded "lightning rod" on the top of the tower, tip being about 20 ft up from the 62ft boom on the Razor and it did nothing for suppressing the hash.
The only thing that works is the lower antennas, below another set of antennas higher up.
When you think about it, the top antenna (say at 100 ft) gets hash at 20 over 9 (just about standard signal level regardless of antennas used), while lower antenna (say at 50 ft) gets NOTHING, zilch, absolutely quiet with no traces of hash. You would think that Hash "signal" 50 ft higher would be also "heard" by the lower antenna, but it isn't!
Now the quantum scientwists can speculate what is going on.

Lab prototype supposedly first went on the air in '80 in JA land. First exported production units hit the U.S. ham store shelves sometime a year give or take later. So I'm told. I wasn't there because around '75 I pulled the plug on ham radio to tend more pressing priorities and bailed away from my short stacks of Collins and Drake treasures for the best part of a quarter century. Until three years ago to be more precise. Got my last brat outta her degree program and my wallet, Dad's turn, decided to jump back in. Took milliseconds to understand that if I wuz gonna play the game the way it's played today Colllins & Drake were history, I'd better do a today radio. 'Way back then I ran with the big dawgs in the cw dx contests so I sed to self, "Go visit some of the those-days big dawgs in the game who are still at it and get up to speed on today radio and radios". Which I did in volume. Felt like I'd stepped out of a time machine actually, but I got the drift.
>
We have a big dawg club (FRCC) relector in which I finally posted a query, ""OK, I'm back guys but there is no way I'm gonna pop $5k for any of the xcvrs you guys are into, maybe later, not a discussion at this point, what decent used radio is out there which is currently available for under $2k I can glom to get back into the game?"
>
Yeah, I know, this is getting to be another rant. I paid for this bandwidth, fuggit, deal with it. Dialed back in the next day and I thought the masses were attacking my inbox, one download after another. Couple dozen responses, "Do a 940 Kelly!!" I'll spare you the gory details but I wound up driving three hours each way from Philly to northern Virginia to lay down $1,250 for a pristine maxed-out 940 from a member of a competitor club. Humpf. The autotuner of course, the computer interface card of course (try to find one of *those* suckers today: As if!) and the entire set of third-party IRC xtal filters of course.
>
Got the damned thing home and hit the "on" button and absolutely nothing

happened, dead, terminally kilt, despite the fact that I'd spent two hours getting operating checkouts and running the thing in enemy 4-land country. Having no clue whatsoever and going into panic mode I figgered I'd screwed the thing up on the rather raunchy three hour trip home and shipped it off to the east coast Kenwood repair facility in Newport News.
>
Cupple days later the Kenwood tech calls, "Mr. Kelly, your 940 is fine, apparently the clock timer was set to "radio off" when you tried to use it." The pore guy tried really hard to suppress his giggles, din work A clueless dipshit is a dipshit, *SELF*, no escape, no way, end of. I'll never live that one down.
>
One thing led to another during the ensuing discussions despite my chagrin, yadda, yadda. Bottom line being that since I'd already shipped the stupid thing to Kenwood I tossed carte blanche at it bought the uncataloged full upgrade of my 940 to it's last production design revision circa sometime in the early 90s when it finally disappeared from the U.S. ham store shelves. The guy billed me for his two-page carefully itemized sixty-something new components installed bill of materials plus his labor all of which totaled a lousy $168 plus shipping and he had it back to me in eight days flat via surface UPS.

Early in my much-noted experience as a Highway Parol radio op we used a 1/4 wave ground plane antenna mounted atop a 350 ft freestanding tower, with the active element insulated from ground in the conventional manner. Often when a storm involving turbulence would move into the area, the three FM 42 mHz receivers squelches would come open and the static would build to a howling cresendo, after which either there was an 'snap', an arc which discharged things or lightning would strike. Theniet would start again, and would repeat several times during a given storm, until the turbulance passed out of the area. The static would desense the recievers so much that it was not possible to receive a car from even a few miles distance while it was happening.
Later the ground plane antenna system was replaced with a colinear type consisting of four folded dipoles mounted on each tower leg, spaced from the top of the tower down. These antennas operated at DC ground with respect to the tower. That was the end of the rain static. I never once heard it on the new colinear antenna.
That antenna system was in use for over 15 years before I got there, and during turbulent thunderstorms it would virtually paralyze the receivers. Fortunately such a storm rarely lasted more than a few minutes.

FCC Order Declines to Include CC&Rs in PRB-1

NEWINGTON, Nov 17, 2000--The FCC has denied an ARRL Petition for Reconsideration calling on the Commission to declare that PRB-1 applies to amateurs living in areas governed by CC&Rs or condominium regulations just as it does to hams regulated solely by local zoning laws. The FCC Order, released Wednesday, also seeks to "amplify" the definition of the oft-cited "reasonable accommodation" phrase in PRB-1 with respect to local land use and zoning.

"The Order provides some additional clarification on the extent of PRB-1 preemption, but it falls short of providing the relief that ARRL was seeking," said ARRL Executive Vice President David Sumner, K1ZZ. Because Deputy Wireless Telecommunications Bureau Chief Kathleen O'Brien Ham issued the November 13 Order under what's known as "delegated authority," the ARRL now is mulling whether to submit an application for review by the full Commission.

Ham was the same WTB staff member who denied the initial ARRL request on the subject a year ago. Sumner said the denial was "not particularly surprising at this point, especially when you're asking the same person to 'rethink' their original decision." The ARRL, he said, believes the issue is critically important and continues to gather additional information and plan on how to present its arguments more persuasively before the FCC.

In requesting that the FCC extend PRB-1 to restrictive covenants, the League said it wanted hams to be free to negotiate reasonable accommodation provisions with local homeowners' associations as they now may do with governmental land use regulators. This week's Order said the League failed to demonstrate any "significant change in the underlying rationale of the PRB-1 decision" that would necessitate revisiting the issue. "In the absence of such showing, we believe that the PRB-1 ruling correctly reflects the Commission's preemption policy in the amateur radio context," the FCC Order said.

The FCC Order said that even if the Commission does have authority to address CC&Rs within the context of Amateur Radio facilities, "this alone does not necessarily warrant revisiting the exclusion of CC&Rs from the Commission's limited preemption policy." The ARRL has argued that since PRB-1 was promulgated in 1985, the FCC has made it clear that it has Congressional authority to prohibit restrictive covenants that could keep property owners and even renters from installing antennas to receive TV, satellite and similar signals. The same principle applies to Amateur Radio, the ARRL asserted.

The FCC Order says, however, that ham antennas are not like over-the-air reception device antennas, "which are very limited in size in residential areas." Regardless of the extent of the FCC's discretion with respect to CC&Rs generally, "we are not persuaded by ARRL's arguments that it is appropriate at this time to consider exercising such discretion with respect to amateur station antenna preemption," the Order said.

In its initial denial a year ago, the FCC said PRB-1 excludes restrictive covenants in private contracts as "outside the reach of our limited preemption," although it strongly encouraged associations of homeowners and private contracting parties to "follow the principle of reasonable accommodation" with respect to Amateur Radio.

The problem of restrictive covenants has been exacerbated in recent years as planned developments have drawn new residents from among the growing number of retired hams, who then learn they may not install a tower or outside antenna of any type. The League's Regulatory Information Branch reports that the topic of restrictive covenants and antennas is one of the most frequently raised by members contacting the ARRL for information.

The FCC Order also took the opportunity to clarify by example what PRB-1 means by "reasonable accommodation" in terms of amateur antennas. The Order says the FCC does not believe that zoning regulations providing for extreme or excessive prohibition of amateur communications "could be deemed to be a reasonable accommodation." As an example, the Order said, "we believe that a regulation that would restrict amateur communications using small dish antennas, antennas that do not present any safety or health hazard, or antennas that are similar to those normally permitted for viewing television" is not reasonable accommodation or minimum practicable regulation.

On the other hand, the Order said, communities wanting to "preserve residential areas as livable neighborhoods" would be free to adopt zoning that forbids antennas "commonly and universally associated with those that one finds in a factory area or an industrialized complex." The FCC conceded that while such rules could constrain amateur communications, "we do not view it as failing to provide reasonable accommodation to amateur communications."

The FCC Order also turned away the ARRL's request to provide greater definition via PRB-1 to protect amateurs from "prohibitive and excessive fees" that localities might impose. "Excessive costs associated with burdensome screening requirements are also often imposed by municipalities seeking a mechanism to preclude amateur antennas, notwithstanding the PRB-1 policy," the League had argued. Such costs "are the functional equivalent of a prohibition of amateur communications."

The FCC Order stuck to the earlier conclusion that the current standards for "reasonable accommodation and minimum practicable regulation" spelled out in PRB-1 "are sufficiently specific to cover

any concerns related to unreasonable fees or onerous conditions." The FCC said that with these guidelines in place, "an amateur operator may apprise a zoning authority that a permit fee is too high, and therefore unreasonable, or that a condition is more than minimum regulation, and, therefore, impracticable to comply with."

The FCC also said that it continues to believe that it should "not specify precise height limitations below which a community may not regulate, given the varying circumstances that may occur."

The Order combined the FCC's response to the ARRL Petition for Reconsideration with its response to a similar filing from Barry N. Gorodetzer, N4IFE, and Kathy Conrad-Gorodetzer, KF4IDH, of Ft Lauderdale, Florida. In their petition, the Gorodetzers asserted that membership in a homeowners' association typically was mandatory, thus rendering moot any argument about "voluntarily entering into private agreements" with respect to CC&Rs.

A copy of the FCC Order is available from the ARRLWeb.

Thanks to all who responded to my posting. Because of continued quite good
receiving performance I think the problem is most likely an open outer braid
connection in one of the co-ax joins. The balun is a Japan RAK rated at 4KW
ssb and 2KW cw so the power available to me should not trouble it. Anyway I
think the antenna will have to come down for proper checking....
Thanks again.

I'm not familiar with that tuner itself, but have heard the brand name
many times. It's probably a good deal if it's cheap. Of course you
always have to take the power ratings with a grain of salt. That will
vary with what you are trying to feed. Usually a tuner rated for 3KW is
good for about 700-900 watts CW. maybe less, maybe more. Just depends.
That doesn't mean a whole lot as all of them will do about the same
power if they are using equal componants. You will need a real brute
tuner to do 3 KW cw. Few qualify. A roller coil is a plus to my way of
thinking as seems more precise, but a tapped coil can be ok as long as
enough taps. If it's cheap, you can try it and if you didn't like , I'm
sure you could get your money back. Pretty good demand for tuners these
days. MK

If a Z0-match exists, the reflections at the Z0-point will be exactly
canceled by complimentary reflections arriving from the load. There
will be no reflections on the coax to the transmitter. The reflected
energy has nowhere to go except back toward the antenna.

The reception would be better if the antenna was outside
and higher. With VHF and UHF height makes the biggest
difference. I wouldn't worry too much about the RG-58 or
grounding your antenna...

2697. A dummy's question on antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-19 00:00:00 UTC
From: Otto Schtierlitz <oschtierlitz@hotmail.com>
Message-ID: <8v8g0n$7je$1@nnrp1.deja.com>
Source record: 176103

I apologize for distracting you guys from serious discussions, but I have a question which all you radio and electronics gurus might help me to answer in a blink of eye. Thanks in advance!

Here it is. I was solving a quiz in our local newspaper and there was a question I could not answer. The question is: "if you multiply the current passing through antenna (A) to the antenna's height (m), how is this production called". So I believe there should be some special name (a term) in radioelectronics or physics for this I�h production, meaning some antenna characteristic or whatever.

I've looked through tons of reference materials I was able to get, including search in Internet, all to no avail. I am absolutely unfamiliar with this field of knowledge, so I believe it would be easier for me just to address this honorable forum for help.

And, oh, one important notice: I've already sent the answers for this quiz, so this particular question remained unanswered, so I am not cheating by asking you. The paper will publish the answers only in two weeks and I am going to die if I don't get an answer for this damned antenna question right now!!!

Thanks in advance!
Otto

Hi Chuck--

I recommend against it. Even if you got the antenna to load properly and not be too lossy, its just too low to be useful. Horizontal antennas are very sensitive to height. At a low height they point almost straight up. Thus they very much favor fairly local propagation.

If you can improve the ground plane by using the wires taped to the trailer roof, that strikes me as your best bet. On the other hand I don't know how practical it is for you to attach the vertical driven element you have.

Perhaps there are more suggestions?

>I Highly and inthusiastically suggest you check out Force 12's V-3 or ZR-3!
(snip) They deserve a look!<

Take a very close look. From what I see (from a distance), it is a very short and fat center-fed vertical dipole with multiple "combination loading" components added to each end to resonate the short vertical dipole radiator on each band of interest. Further, I'm guessing there's a frequency-compensated matching network of some sort at the center to transform the very low impedance of the short radiator into a 50-ohm system. A wound feedline choke is probably used at the base to allow the feedline to exit without becoming part of the lower half-element. Can anyone who's looked more closely confirm or disclaim my admitedly speculative assessment?

It's no secret that, as a dipole element grows significantly shorter than .25-WL, efficiency drops rapidly due to a near-exponential increase in losses. Of course, that doesn't mean a really short dipole won't work stations: See Shiller, T, "Everything Works, QST, July, 2000, pp47-50. Heck, last spring, I got an S9 report on 20 meters running 100 watts into a 3-foot long meander-line dipole.

Never the less, a short heavily loaded multiband vertical is just that, and even with very careful management of losses, you can only fool mother nature to a point!
Will a ZR-3 short dipole work better than a lightbulb? Of course! But, I'm not sure how the ZR-3 can possibly rise much above Tom's "Missing A Lot" catagory in performance--short of employing a combination of superconduction and black magic.

i ahve a atas-100 antenna and would like to use it as a base station antenna. space is limited. i was told i need to spread out 8 32' radial wires as a ground plane or counterpoise. is this right?

can anyone advise me on the proper install of this ant for stationary use? i'd hate to have to put a $100 shell of a vehicle in my back yard to mount it on just to have the proper ground.

hey chuck what you could do is rig some PVC poles on each corner of the RV and string a loop around it or do a bend dipole then when you need to take off you can just unhook the poles and stoe them inside good luck

There sure are, and one is that your assertion is not wholly correct.

As a Novice in 1957 I used a 40 meter dipole that was never above 10
feet in height at any point, and while I didn't make WAS on 40 CW I sure
came close in the three months that I was a Novice. More recently, I use
as my motorhome portable antenna, an autotuner-fed 60 ft wire that
attaches at the roof level of my motorhome and runs to whatever support
I find available 60 ft away, usually a collapsable 10 ft aluminum tent
pole that I carry for the purpose, lashed to a tree, shrub or whatever.
The counterpoise is 40 ft of enameled copper wire lying on the ground
under the motorhome, laid in a rough configuration to fit under it. I
works well, and I never have problems making contacts.
Sure, the major radiated component is something like NVIS. Its
inevitable, but there is still a useful component that takes off at

lower angle. And for ~200 - 500 miles it works very well as NVIS.
I also have a Hustler whip system on th back bumper (fiberglass tail on the MH) to use when not set up in a campground.

I'm not sure I'd want the antenna incorporated into my motor home rubber roof for other ressons, though. One is the possiblity of high voltages being developed at some frequencies that could cause arcing to hidden metal and creating a fire hazard.
I once read of a ham who had an attic-mounted dipole fed by a 150 watt AM transmitter that caught his house on fire with it. That's much more likely with a full carrier tramsnitter such as an AM rig than with SSB, or even CW, since when an AM carrier is on it just sits there and 'fries' until standby time. But one still usually transmits full carrier at some time when tuning up. It's certainly not out of the question. Attic dipoles and any roof antenna installation should be carefully done with such hazards in mind keeping the antenna well insulated and isolated.

Chuck,
Two problems with the dipole on the roof is (1)interaction with metal in the motorhome roof/structure and (2) low elevation will give it primarily a vertical lobe on most of the lower bands. Now this is not bad if you are looking for local coms.

An approach you may want to take is to get a vertical pole and run either an inverted vee or inverted-L. I have used an end-fed 66 ft wire fed against the ground and was able to work 160-10m QRP fairly well with the max height of 25 ft.

For a support mast I would recommend you look at getting one of the paint extention ploes (you can find at many hardware stores) that is 23ft long. Cost is about $39.

For a little more height you can make a telescoping mast from aluminum tubing from Texas Towers (about 33-40ft) for under $65.

For your wire you can use the STEALTH flexweave wire about #26 guage from WIREMAN.

Hi Bill:

Thank you for the comments.

I would like to respond to this from two perspectives. One is understanding what happens at an antenna and the other is from the derivation of the

general transmission line equation, re: Johnson, since I know you have the book to look at as I discuss it.

First as a general comment, in the steady state, the total voltage and current developed across a physical load (ZL) connected directly to an amplifier is exactly the same as that developed at the input to a transmission line having an input impedance equal to ZL. However, in one case we have a circuit problem and in the other we have a combined circuit-transmission line problem. The issue is relating the circuit-transmission line problem to the purely circuit problem.

Let's assume that we have an antenna connected at the end of a one-wavelength lossless transmission line. Let's assume that there is a steady state forward traveling voltage arriving at this antenna. What is the total steady state voltage developed across the antenna? It is equal to the vector sum of the steady state forward voltage and the steady state reflected voltage. This is demanded by general transmission line theory. At this point, we see that the total voltage developed at the end of the TL is a direct function of the reflected voltage developed at the end of the TL. Why would TL theory work any differently at the input end of the line? In fact, it does not. At the input end of the transmission line, if the amplifier output impedance is not equal to ZO, there will be some level of voltage reflection (or re-reflection) which must be a component of the total voltage developed at the line input as TL theory demands.

The problem that most people have is that they consider only the steady state conditions and only understand that there is a forward and a reflected voltage at the line input. The real issue is understanding how these forward and reflected voltages develop.

In the example above, at the input to the line, the total voltage will be the same as the total voltage at the antenna since the TL is lossless and one-wavelength long. At the input to the transmission line, what voltage components comprise this total voltage? Obviously, they are the steady state forward and reflected voltages, which are exactly the same as those which exist at the antenna. So, at least at this point, we should agree that the total voltage at any point on the transmission line is equal to the forward voltage + the reflected or rearward voltage. The input impedance at the input to the transmission line is equal to the ratio of total steady state voltage / total steady state current.

So now, the issue is what voltage components comprise the total steady state voltage at the TL input? And, does the re-reflected voltage have any effect on the TL input impedance? In order for the re-reflected voltage to have an effect on the TL input impedance, it must be a component of the total voltage developed at the input to the TL. My post of Friday, indicated that the total voltage at the input to the TL is comprised of three components: 1) The forward source voltage which is a function of ZO, 2) the reflected voltage and 3) the re-reflected voltage.

Let's look at the general transmission line equation as presented by Johnson:

The equation is (4.23) on page 100: The total voltage at any point on the line is given as follows:

E = A B

where A = Eg Zo / [(Zo + Zg) (1 - rhoA rhoG e^-(2 gamma L)]

and

where B = [e^-(gamma x) + rhoA e^-(2 gamma L) e^+(gamma x)]

Eg is the source voltage. rhoA and rhoG are the antenna and source reflection coefficients, respectively.

The equation for total voltage at any point on the line is explicitly a function of rhoG, which is the reflection coefficient of the source indicating the level of re-reflected voltage is in fact a component of the total voltage. The input impedance of the line is therefore a function of the re-reflected voltage.

Consider the derivation of the equation further beginning on page 98 and the three voltage components comprising the total are clearly evident. One is the forward source voltage, a function of Zo. Vsource = Eg Zo / (Zo + Zg). The other two components are the reflected and re-reflected voltages as discussed on page 99.

To see all of this we need to look beyond our view of only the steady state. The amplifer really only sees the Zo of the TL and this is the basis for the true forward source voltage. The other voltages in the TL only develop as a function of reflections and re-reflections on the line. No physical impedances in the system change, only the total voltage and total current.

The towers (ROHN) are double hot dipped galvanized. There is nothing (that
I've ever seen) in their engineering and parts catelog about coating with
oil, or tar.

What they do have is a detailed section on prepareing the bottom of the hole
to get proper drainage for the tower base legs.

I'd be a bit concerned about using oil to coat the bottom as it would
migrate down and probably contaminate the material at the bottom and hinder
drainage.
It would depend on how much were used, but oil is not a permanent cure.
If I felt the need to coat the bottom of a tower (non galvanized like the
old American Standard, or American Steel ?), I'd use a material that would
not flow after application. Tar would be one that comes to mind.

I'm past 60 and still do all my own climbing. (97 foot ROHN 45G and a 90
foot American Standard) My wife put her foot down though and I had to quit
climbing towers for the young guys.<:-))

The past few weeks I've been climbing that 45G up to 6 times a day. I seem
to be getting in pretty good shape <G>Antenna installation and working on
the multiple rotor system.

The system uses concentric masts and will eventually have a rotor for each
once I get my machine shop set up.

2713. Antenna spacing

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-19 00:00:00 UTC
From: Roger Halstead <rdhalste@tm.net>
Message-ID: <QnTR5.505$EI3.47941@newshog.newsread.com>
Source record: 176169

I decided I'd have enough room at the top of the mast (above the top of the tower) to install a quadature array of UHF TV antennas.

The spacing for the 440 antennas of comparable length and number of elements is about 6 feet. Soooo...I figured that 5 feet should work fairly well.

Well, they did work kinda sorta, but that thing has more side lobes than any system I ever used. At least three of the side lobes (on each side) are down, only slightly, from the main lobe. The system certainly has more gain than a single antenna (even on a couple of the side lobes.

I'm guessing that the extra and strong side lobes indicate inadequate spacing.
I could go out to 10 feet, but it would end up as a stacked pair as I do not have the room for the extra five feet of vertical spacing.

I've not found any information on spacing these in the E and H plane.

Any ideas?

Ed,

Thanks! Your numbers proved the key. Your director length
blew me out of the water - I never thought of making it that
short. But it got me to thinking - so I installed a replacement
director cut to 99" and bingo! (Thats about 12% off the DE)
I still don't know what I should get from the antenna if built
to spec in terms of swr bandwidth, but at this point I am getting
the expected performance from the gamma match. I just
couldn't tune it to where I wanted until I cut that director way
down. The purpose of this antenna was to experiment with the
gamma, and my focus on the problem was always on it (the gamma)
rather than on element length. I figured there was something wrong
with the gamma I built. Now I can "play"!

I do undertsand that the widening the swr bandwidth impacts gain
and F/B, and the modeling programs show that. But I never knew
you could reduce the director length as much as your numbers
showed (your director is about 73" long) and still get some gain
(about 4DBd). I get about 1 Db more with the 99" director
at enough swr bandwidth for my purposes. So, a hearty thank you!

> forward and reflected voltages develop.

I know exactly how the steady state is developed, and I don't need (or want) any "lectures" on this subject.

In the steady state the power delivered to a 10 ohm resistor at the output of the amplifier, and the power delivered to the same 10 ohm resistor at the end of a 1 wavelength coax are exactly the same. The amplifier looks out and sees exactly the same impedance in both cases. That is the essence of Johnson's equations.

And as for Johnson's Equation 4.23, I understand all of that discussion and derivation as least as well, and (I'm beginning to think) maybe even better than you do. I know that it is a steady state solution and that the final result is exactly and precisely what I have been posting.

Believe it or not, I am an expert on Equation 4.23.

This "thing" is obviously turning into some kind of very unpleasant macho pissing contest and dominance game, and I really don't want anything more to do with it.

I stand by what I have been saying, and for me personally that is the *end* of it.

Hi all
I hope this is the correct news group to field this question.I have been made an offer to buy an antenna tuner that is an older unit.It is described to me as a 3 KW tuner. Name is Murch model UT 2000A.Does anyone know anything about this tuner.Any info or experiences with this tuner will be greatly appreciated.The asking price is very low so it will not be a big cost.I just would like to know a little about it.I know it is in working order, and have been invited to try it out to see it work.
Thanks for any info.

A length of an antenna in metres is a measure of its radiation resistance. To multiply by a current in amperes gives something which has measurement units of volts. Something to do with field strength laid down by a radio transmitter when 1 ampere flows through a wire length of 1 metre ?

Source record: 176179

Hello,

Does anyone have a suggestion for a design of antenna to operate satellite on 401 or 406 MHz (ARGOS and GOES respectively). I am obviously looking for a design which directs most of the energy above the horizon (say from 15 to 90 degrees). This antenna needs to be physically small (say max. of 3 feet tall and 1 foot wide) with no ground plane required.

Is a quadra helical design suited for this application? Any web pages or other info. with design parameters would be appreciated.

Cheers,
Bruce

I came in the middle of this and did not see the original, nor do I find it on my server.

In plain terms, the power just keeps going back and forth with bits getting radiated at the antenna each time it gets there and bits getting turned into heat by resistive losses.

If you had a theoretical lossless line, all of the power would get radiated... eventually, although some would be more than a bit late.

Starting with a lossless line and a conjugetae match *at* the transmitter, lets say that 50% of the power is reflected at the antenna. 50 watts would be radiated and 50 watts would be reflected back tot he transmitter, where due to the cojnugetate match it would head back out again, in phase with, and added to, the output power. We'd now have 150 watts on the line andwhen getting to the antenna we'd find 75 watts radiated and 75 watts reflected back.

If you do the math you will find 100 watts being pumped into the line and 100 watts radiated from the antenna. The feed line would have 200 watts and they are real.

Unfortunately we don't have lossless lines, some and the mismatch at the antenna would result in some of the reflected power probably ending up on the outside of the shield which would radiate. Most of the power is lost in the form of heat as it runs back anf forth.

But if the run is relativley short and of good quality and low loss, most of the reflected power (assuming a match at the transmitter end) will end up being radiated from the antenna.

However that's not all good as there will be many cycles (depending on frequency)which are well delayed from the initial radiated power.

In CW and SSB these are not usually a problem, but with data and television they can be real problems.

Now, if you were talking about reflected power and no tuning network (as I understand it) which eliminates tube type equipment, then it depends on the sign of the returning power. Then you can end up with either excessive

voltage, or current in the final network and transistors. The power is again reflected, or most of it is, but the excess voltage, or current can create a bit of mischief .

2726. Antenna spacing

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-19 00:00:00 UTC
From: Roger Halstead <rdhalste@tm.net>
Message-ID: <PsVR5.1710$Ur5.178836@monger.newsread.com>
Source record: 176182

I made this post some time back, but I never saw it on the newsgroup, yet several posts made later did show up, so my apologies if this comes up twice.

I decided I'd have enough room at the top of the mast (above the top of the tower) to install a quadature array of UHF TV antennas.

The spacing for the 440 antennas of comparable length and number of elements is about 6 feet. Soooo...I figured that 5 feet should work fairly well.

Well, they did work kinda sorta, but that thing has more side lobes than any system I ever used. At least three of the side lobes (on each side) are down, only slightly, from the main lobe. The system certainly has more gain than a single antenna (even on a couple of the side lobes.

I'm guessing that the extra and strong side lobes indicate inadequate spacing.
I could go out to 10 feet, but it would end up as a stacked pair as I do not have the room for the extra five feet of vertical spacing.

I've not found any information on spacing these in the E and H plane.

Any ideas?

Could you elaborate a bit? It has occurred to me that concentric masts, with the big multi-band yagi on the outer mast and the vhf/uhf beams on the inner (taller) mast, would be nice, but I have not seen any commercial rotors that would work with the outer mast, allowing the inner to pass through. And everyone else that I mention it to seems to think that I'm daffy.

Hummm, sure those aren't vortex disturbers? Many smaller jets etc use those. I haven't really noticed the sharp points on too many, but guess I didn't look too hard. A vortex disturber looks like a short metal strip sticking up off the wings etc. You will see a whole row of them on many planes like learjets etc. They would probably look kinda like little probes from a distance. But, these may be totally different items from what you describe. I'll have to look into that sometime. The vortex disturbers do as their name describes. The reason I'm familiar with these is a friend of mine works on learjets. I went over there one time, and noticed all those short strips all over the wing, and asked him what they heck they were. Weird looking little things. But you can tell those as they just look like a strip of metal like they were cut out with scissors. MK

Actually, thinking about it, if the ones you describe point aft, they
are probably different from the disturbers. The vortex disturbers point
straight up nearly. MK

Many planes will build up a corona that nearly surrounds the jet. Or the front end anyway. Many times pilots can see the blue glow all around the windshield, windows etc. Looks pretty wild at night.
>

Huumm, kinda surprised insulated wires would help that much. Doesn't seem to make a whole lot of difference here on the ground. But then again, I've never really tested it to compare. All my current ant wires are insulated, but I still hear the noise from time to time I think. I don't notice much noise at all from my small 3 el yagi for 2m. But it has very rounded element ends. It's one of those 2m beams that Alex sells at City electronics. A very nicely built yagi I think. I think some friend of his makes them. MK

Two items, one is a static wick, normally black in color with what appears to be loose string hanging out the ends. These are used to bleed off static charges. What you are referring to are Vortex Generators. On the Lear 23 with the original wing they were mounted on both the top and bottom of the wing. Later models had them only on the top and they were removed entirely if a MK1 wing was installed. The are a NO GO item if more than 3 are missing as I recall.

Many times while descending through a snow storm I have seen continuos balls of blue static emanating from the nose of the tip tank and along the windshield pillar.

I hold Commercial ASMEL with instrument. Type ratings include LearJet, Cessna Citation, and DC3 ratings. The old prop jobs use to get rings of static around the edge of the prop. At 8000 feet in the winter between Buffalo and Detroit it would be so bright on the old Beech BE8T's it would light up the cockpit.

Let me suggest an antenna called the Texas potato masher. A quick net search should locate it for you, it is a modified eggbeater.

>the lower antenna, but it isn't!

The reason you can't hear the noise, is the energy of the noise is
very very low. It is caused by tiny corona discharges from the
elements in the antenna. All the charges do is leak off into the air
around the antenna. It isn't a "path" up to the clouds in the sky, if
it was you'd be in deep crap when the ionized air suddenly discharged
the cloud!

That's why a quad is purported to be quieter than a yagi. The corona
on a quad is at a low impedance point, not like a yagi with the tips
of the elements sticking out in the air. The yagi is closer matched to
the exteremly low current high voltage discharge caused by the high
voltage gradient between the earth and the clouds.

The LAST thing you want to do is add more corona near the antenna,
although if you add it higher up it will "neutralize" the charge seen
by the lower antenna and stop it from having corona streamers.

> If it exists, where does it go?

I don't understand the question. The reflected energy stored in the transmission line is dissipated/radiated *AFTER* the transmitter is disconnected. I've already shown that 300 joules is stored in a one second long transmission line when the SWR is 5.83:1 and the transmitter is putting out 100 joules/second. There is a transient condition when the transmitter is turned off. The reflected energy is dissipated and radiated during that transient time.

Chuck,

Why not a screwdriver? I have seen in QST, as well as installed these on motorhomes in a semi-horizontal position. They work very WELL! I have even seen them mounted on a hinged mount so they could be used either way--horizontal or vertical. Even heard of motorized raise/lower mechanisms so they could be put into the desired position as well as resonated from the driver's seat!

> Alan KB7MBI in Woodinville, WA

I'd go with your idea if possible. A dipole at 20-25 ft will work fine
for 85% of the stuff. In the past I just tried to camp next to a few
trees, and I would string a dipole between tree branches. Rarely was the
antenna over 20 ft, ans this was usually 80/40 meter dipoles. Worked
great for what I do. "Mostly close in" What I have now, but haven't
used yet is a drive on mast support. A friend of mine made it from ship
steel down at the shipyard. It's indestructable. It's made to be a
perfect fit with either fence top rail, or the rat shack mast sections.
I use the fence rails myself as they are cheaper. The only drawback to
fence rails are they are 10 ft long usually, and the rat shack masts can
be had in 5 ft sections. Maybe easier to carry. I can drive over this
ramp thing, and the mast is not going anywhere. So now I can have a good
mast anywhere I go. No trees required.
And the mast holder could be used for about any type antenna. You could
even have a small beam, and turn the mast to point. It's that sturdy.
Also I'd expect any antennas mounted close to metal to work poorly. For
about the same reason you don't want the coils or whip on a bugcatcher
close to metal. You'll couple to the body and will act like a big RF
soak...g The SWR etc, might look fine, but the radiation will be in the

league of a dummy load. I'd try to avoid that at all costs. A dipole strung away from the camper likely wouldn't have this problem to any large degree. The drive on mast holders can be bought in QST I think from one place. Fairly similar to what I have. Luckily mine was free. Helps to know people at the shipyards where they repair ships...g I did a little work there running a plasma cutter for a while. Cuts thick steel like butter and puter controled. It cut the base of my ramp. MK

Otto Schtierlitz wrote:
"If you multiply the current passing through the antenna (A) to the antenna`s height (m), how is this called?"

Field intensity of an "elemental antenna" (small in terms of wavelength) is directly proportional to the current. Field intensity is also directly proportional to the length of the element.

The length should only be a few degrees or less so that the current may be, for purposes of calculation, considered uniform.

An appropriate name for the product of current and length is: Ampere Meters

The (A) and (m) Otto gave hint at this result, but it needs the qualification of short with respect to wavelength, but no limit on current.

Best regards, Richard Harrison, KB5WZI

2755. Why did Rohn discontinue the foldovers?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-19 00:00:00 UTC
From: Peter Bertini <commquart@erols.com>
Message-ID: <8va3uu$4b4$1@bob.news.rcn.net>
Source record: 176211

Anyone have information on why Rohn discontinued the FK series?

Was it a lack of sales, or safety related issues?

I called Rohn the other day looking for info on my FK25 foldover section,
and the person I spoke to didn't know they ever made a foldover kit for the
25G or 45G series!

I need info on the hinge bolts used in the FK25, size, specs, etc. so I can
replace
the old ones in the used section I just picked up with proper new ones.

Pete

2756. Base Insulator for Rohn 25G Vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2000-11-19 00:00:00 UTC
From: WR4T <wr4t@fuse.net>
Message-ID: <t1h5pbfp990rbd@corp.supernews.com>
Source record: 176212

I was wondering if any one has any ideas on how to fabricate a base insulator for a 160M vertical made from ROHN 25G. The factory base insulator requires a special tapered tapered 10ft base section and then an expensive insulator together they run over $1200. I was thinking about other ways to fabricate an insulator.

One thought was to use a large sheet of HDPE under the standard BCP25 concrete base plate. However the HDPE plate about 8" thick 22x22 was over $600 dollars.

Any ideas thoughts on a less expensive alternatives (Not interested in shunt feed need insulated base).

Thanks,

T.R. WR4T

Doc wrote:
"Field strength---"

I agree that field strength is proportionally produced so long as the height (length) of the antenna is only a few degrees or less.

It happens because a straight conductor carrying an electric current produces a magnetic field proportional to the current. A varying current creates a varying magnetic field which begets a varying electric field which creates a varying magnetic field etc.

The magnetic field intensity is: H.
H = 2I / r
I = amperes
r = distance from the wire in meters

The magnetomotive force around the current carrying wire is 4 pi times the current. No limit is placed on distance from the wire, this is an integral and it makes no difference how large the circle around the wire is.

The question didn`t specify which product was to be named. The immediate product is volts times amps, but this produces field strength

Best regards, Richard Harrison, KB5WZI.

If you can get quarter wave (234/freq in mhz), or odd multiples of a quarter wave, ground radials laid out in as uniform of a pattern as you can get, this will work better. 120 radials would be nice, but just put down at least 4. I have 48 65' and 48 135' radials under my 75 and 160 inverted L's. They work very good.
Good luck, Mike> WE0H.

If you have a recent manufacture set, see if it is cable ready.. If so,
you may have the switch in
the CABLE rather than the ANT positition. Cable channels above VHF are
different than the
television frequencies.

They are converted into heat in the fiber optic cables.

David, K3BHJ wrote:
"Clap your hands once when you are in the center of a 10,000 ft radius totally reflecting sphere."

You will hear echos repeat until the clapper soaks up so much sound that it`s no longer perceptible. Sound velocity depends on several variables and we don`t know how absorbant the clapper is.

Best regards, Richard Harrison, KB5WZI

2762. Re: Tower Guying question (Stainless steel or galvanized?)

Tim Taylor wrote:
"I have access to both stainless steel and galvanized steel hardware
such as shackles, bolts, and pins available for use in guying my tower."

Use the galvanized hardware if you ever intend to loosen or tighten any
threaded parts later on. Stainless deforms and binds. Galvanized does
not.

Best regards, Richard Harrison, KB5WZI

Are they still using 42 Mhz? All the PDs around here moved up the spectrum years ago
although I think the fire board is still in the 40-50Mhz band. .
